Abstract: Teachers' conceptions about human evolution have been a matter of intense research by Quessada and Clément (2010) in the context of the European BIOHEAD-CITIZEN project. Having in mind the socio-cultural links between Portugal and Brazil, in the present paper we extended the BIOHEAD-CITIZEN study to Brazilian teachers and compared with the equivalent Portuguese sample. The BIOHEAD-CITIZEN questionnaire was applied to 368 teachers and future teachers from Braga district (Portugal-Pt) and 300 from S. Paulo State (Brazil-Br).

Results show a stronger influence of religous values in the Brasilien group as compared with the Portuguese one, though both groups are aware of the natural selection role in evolution theory. Furthermore, significantly ($p<0.05$) higher percentage of Brazilians (67.0%) refer God as being in the origin of mankind as compared with the Portuguese (45.5%). Similarly, 73.3% of the inquired Brazilians believe in God influence for the creation of life as compared to 49.2% of the Portuguese respondents. Although the Portuguese cultural influence in Brazil is strong (for about 500 years and having the common Portuguese language), these results show that the Brazilians, rather than the Portuguese, put in evidence their religious values, which comes along with the existence of more Agnostic/Atheist in Portuguese (9.4%) than in Brazilians (6.4%) samples.

Keywords: Evolution, Creationism, Human origin, Teachers' conceptions.

INTRODUCTION

The teaching of Evolution of life on Earth, particularly the Human origin, is a matter of great concern nowadays and in some countries it has been "*concealed, denied, or confused with theories not testable by science*" (IAP, 2006: 1). In a large study involving 14 countries, Quessada and Clément (2010) have shown that national school programmes of four countries (Algeria, Burkina Faso, Lebanon and Morocco) never mention biological evolution, whereas other ten countries refer it either in upper secondary school only (Cyprus, Romania, Senegal and Tunisia) or in primary and secondary school (Estonia, Finland, France, Hungary, Italy and Portugal). Regarding specifically Human Evolution, only eight of these fourteen countries refer it in their school programmes. In other countries, as in Greece, Human Evolution is present in the national programme but often it is not taught in school (Lakka & Vassilopoulou, 2004; Prinou, Halkia & Skordoulis, 2007). Other studies about teaching Evolution have taken place in several other countries – in Spain (Jimenez-Aleixandre, 1994, 1996; Barberá, Beatriz & Pérez-Pla, 1999), in China, USA and URSS (Swarts, Anderson & Swetz. (1994) – often assuming the importance of the social context for the national programmes and textbooks contents (Skoog, 2005).

In a large European project BIOHEAD-CITIZEN ("Biology, Health and Environmental Education for better Citizenship" – FP6-STREP CIT2-CT-2004-506015) involving 19 countries from Europe, Africa and Middle East (Carvalho, 2004; Carvalho and Clément, 2007), the interactions between social context factors and teachers' conceptions about Evolution has been a matter of research by Quessada and Clément (Quessada et al, 2007; Quessada, 2008; Clément & Quessada, 2008, 2009 – all referred in Clément & Quessada, 2010), putting in evidence the degree of believing in God and of practicing religion, the country economical level and the teachers' level of training.

Having in mind that Brazil was a Portuguese colony until 1822, having high cultural influence (especially the common Portuguese language) but also with strong differences (especially the multiculturalism in Brazil), in the present study we extended the BIOHEAD-CITIZEN study to Brazilian teachers and compared to the equivalent Portuguese sample, focusing on the religious beliefs in the origin of life and human kind.

METHODOLOGY

The BIOHEAD-CITIZEN questionnaire used in this work has been validated and applied to several countries (Carvalho & Clément, 2007; Munoz et al. 2009) was applied to teachers and future teachers from Braga district (Portugal-Pt) and from S. Paulo State (Brazil-Br). In either country the questionnaire was applied to six samples of pre-service teachers (Pre) and in-service teachers (In) of primary school (P), and of secondary school, teaching Biology (B) and Portuguese (the national Language, L). This makes six subsamples in each country (Pre-P, In-P, Pre-B, In-B, Pre-L and In-L) which were well balanced as shown in Figure 1.

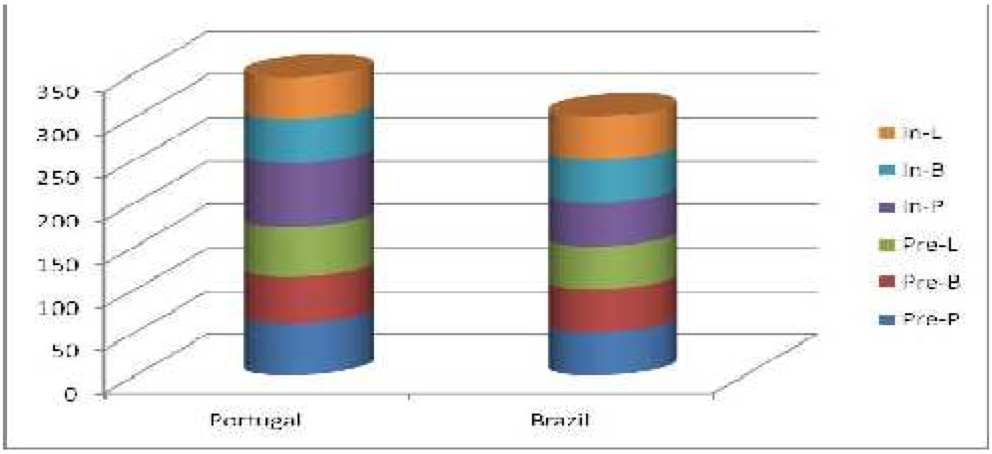

Figure 1: Teaching group distribution in both Portuguese and Brazilian samples.

The sample size (368 Pt and 300 Br), the percentage of women (82% Pt and 88% Br) and the age mean (32 years old either Pt or Br) show the good balance between both Portuguese and Brazilian samples. Figure 2 shows the age distribution of Portuguese and Brazilian participants, where the 21-30 years-old group is the largest one in both samples.

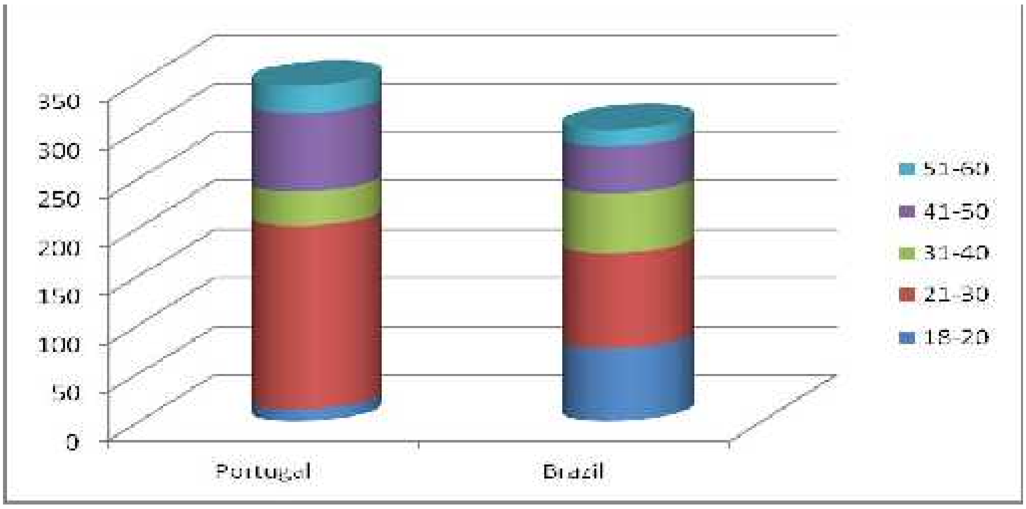

Figure 2: Age distribution in both Portuguese and Brazilian samples.

RESULTS AND DISCUSSION

The majority of responders in both countries were shown to be Catholic (76.4% Pt and 67.4% Br), but Protestants (7.4% Pt and 11.1% Br) and Agnostics/Atheists (9.4 Pt and 6.4 Br) were also present in both samples, whereas Muslims and Jewish were absolutely absent (Figure 3).

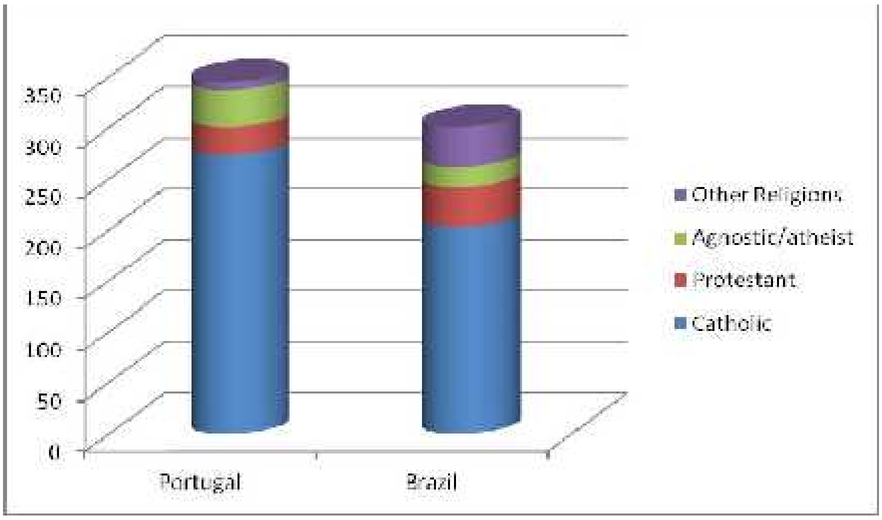

Figure 3: Religious faith distribution in both Portuguese and Brazilian samples.

When asked about believing in God (likert scale: from "I believe in God" to "I don't believe in God") results showed the Brazilians were greater believers than the Portuguese (Figure 4A.) The participants were also asked about their level of religion practice (likert scale: from "I practice religion" to "I don't practice religion") and the Brazilian group said to practice more than the Portuguese did (Figure 4B).

A B

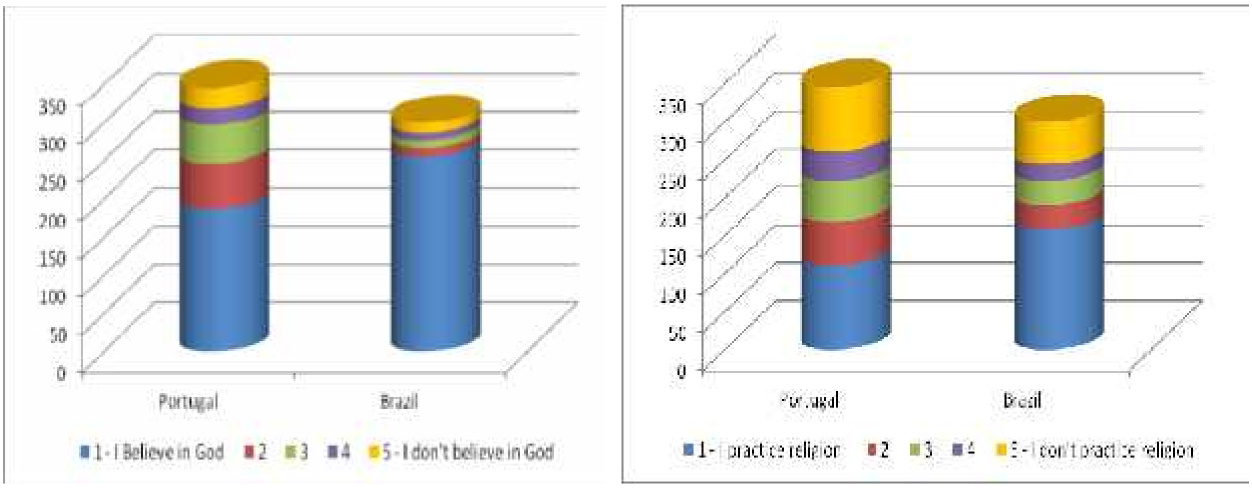

Figure 4: God believers (A) and religion practice (B) in both Portuguese and Brazilian samples.

Of the 15 questions on Evolution, questions A64, B28, B43, B48 were those with stronger contribution for the axes in the principal components analysis (PCA). Therefore they were preferentially chosen to be used for the comparative analysis on Evolution conceptions between Portuguese and Brazilian samples. The statistical analysis was carried out by using the Software Package for Social Sciences (SPSS, version 17).

For the analysis we put the itens "Great importance" and "Some importance" together, contrasting with the itens "Little importance" and "No importance at all" also put together. The answers of Portuguese and Brasilien respondents show that the former (46.8%) give significantly ($p<0.05$) lower importance than the latter (78.6%) to the importance of "God" in species evolution (Question B48, Figure 5A). However, both groups do not differ signifcantly ($p>0.05$) about the importance of the "Natural Selection" in the evolution process: 94.0% and 86.3% of the Portuguese and Brasiliens responders, respectively (Question B43, Figure 5B).

A – B48 **B – B46**

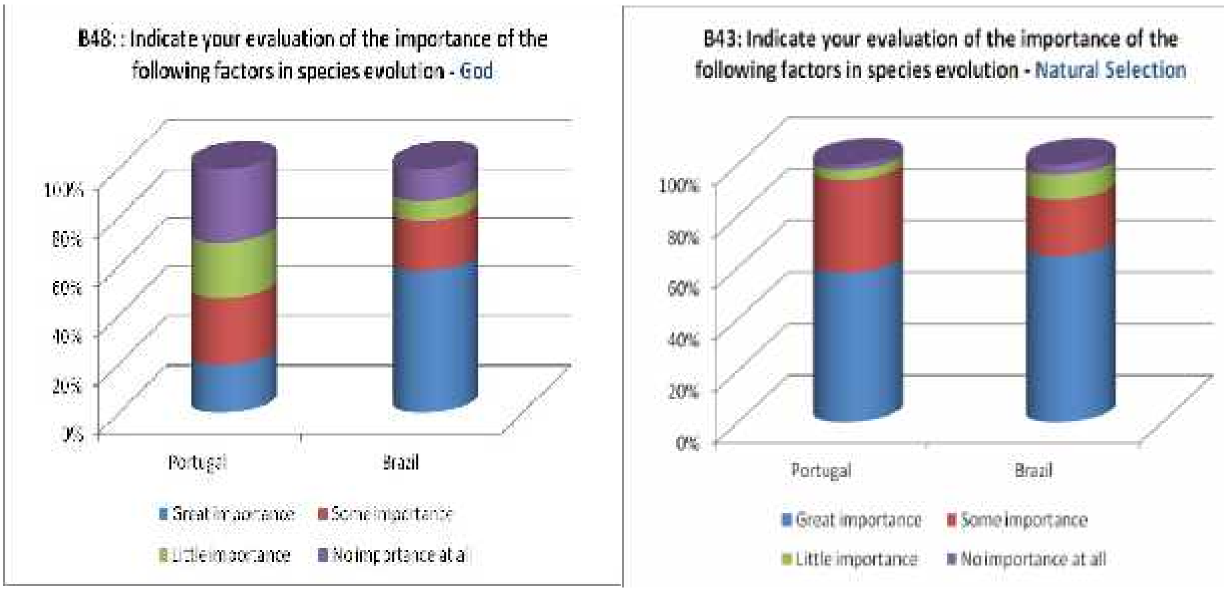

Figure 5: Proportion of Portuguese and Brazilian responders to questions B48 (God influence in evolution) and B43 (Natural selection in evolution).

These results show a stronger influence of religous values in the Brasilien group as compared with the Portuguese one, though both groups are aware of the natural selection role in evolution theory.

Similarly, a significantly ($p<0.05$) larger percentage of Brazilians (67.0%) refer God as being in the origin of mankind as compared with the Portuguese (45.5%) (Question B28, Figure 6A). This is in agreement with the Question A64 (Figure 6B) where, again, 73.3% of the inquired Brazilians believe in God influence for the creation of life as compared to 49.2% of the Portuguese respondents.

A – B28 **B – A64**

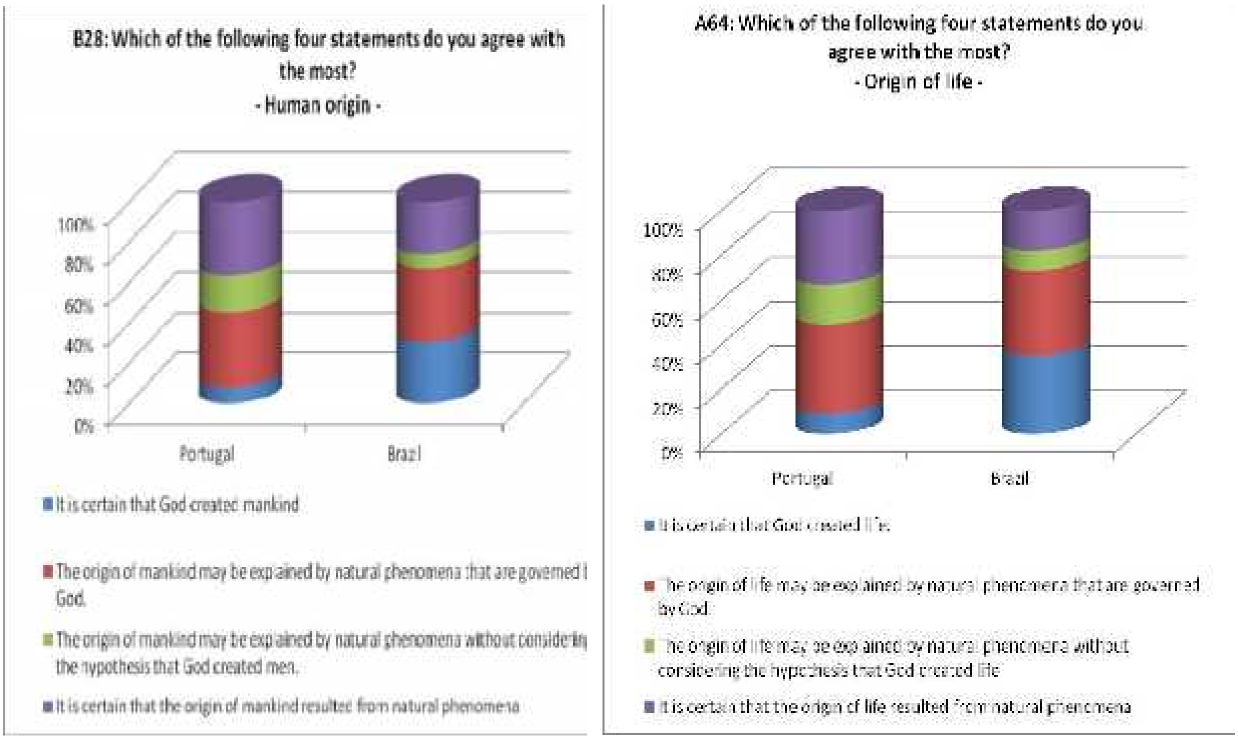

Figure 6: Proportion of Portuguese and Brazilian responders to question B28 (God influence in humankind evolution) and A64 (God influence in life origin).

Although the Portuguese cultural influence in Brazil is strong (for about 500 years and revealed by the common Portuguese language), these results show that the Brazilians, rather than the Portuguese, put in evidence their religious values, which comes along with the existence of more Agnostic/Atheist in Portuguese (9.4%) than in Brazilians (6.4%) samples. Really interesting is the fact that more Portuguese (84.4%) than Brazilians (81.2%) declared to be Christians, although their religious convictions seem to be irrelevant regarding the evolution process. In fact these results confirm our preliminary studies (Araujo et al., 2009; Caldeira et al., 2010) showing that Brazilian teachers live with the evolutionist and creationist conceptions, apparently without conflict.

ACKNOWLEDGEMENTS

This work had the financial support of the European Commission project FP6 BIOHEAD-CITIZEN (CIT2-CT-2004-506015) and the Portuguese Foundation for Science and Technology (FCT) at CIEC (unit of R&D 317).

DIFFICULTIES CHEMISTRY STUDENTS EXPERIENCE DURING THEIR FIRST SEMESTER
- *PREDICTING SUCCESS* -

Katja Freyer[1], Matthias Epple[1] and Elke Sumfleth[1]
[1]University of Duisburg-Essen, Germany

Abstract: It is generally known that student success in chemistry is rather low. Approximately one fourth of freshmen will not succeed the course in general chemistry that is offered in the first semester of studies. Regarding the entire course of university studies - from the first through the last semester - this low student success is also reflected in dropout rates, since approximately every third student ends their studies before completion.
This study investigates the qualification first-semester students in chemistry bring to university. To do this, questionnaires have been developed to determine the students' attitudes towards their studies, their cognitive abilities, and their subject-specific qualifications at the very beginning of the first semester. At the end of the first semester, results from the final exam were obtained and the students were divided into two groups: those who passed the exam and those who failed. With the help of binary logistic regression, the passing of the final exam was able to be predicted. The grade from their secondary school graduation certificate, scores from a chemistry knowledge test and a test for measuring deductive thinking as well as the course of study could be included in a regression model correctly collating 77.7 % of freshmen to the successful and less successful student groups, respectively.

Keywords: Chemistry, freshmen, difficulties, prediction of success, binary logistic regression

INTRODUCTION

The rate of German university students dropping out of chemistry without changing to another subject amounts to 31 % (Heublein, U. et al., 2010). Most students leave university due to difficulties in performance and lack of motivation (Heublein, U. et al., 2010) caused by false expectations of their studies (Heublein, U.; Spangenberg, H. & Sommer, D., 2003). The highest dropout rates in natural sciences studies are found during the first semesters at university (Heublein, U.; Spangenberg, H. & Sommer, D., 2003) since the beginning of studies is accompanied by a great number of problems, like adjusting to a new environment and social challenges that have to be managed all at once (Gerdes, H. & Mallinckrodt, B. 1994).
This dropout rate problem is not specific to Germany: Other European countries have excessively high dropout rates as well. Ulriksen, Møller Madsen & Holmegaard (2010) state that around one third of students end up their studies before the scheduled time.
Low student success is an important issue at American universities as well, as only approximately 70 % of freshmen in chemistry pass the final exam in general chemistry at the end of first semester (Legg, Legg & Greenbowe, 2001; McFate & Olmstedt, 1999).
There exists the need to find factors that, as soon as studies begin, can identify those students who will be able to pass their studies and those who will not.

There have been a lot of approaches for determining the factors leading to success. The attempts date back to 1921 (Powers, 1921). Up to now, several variables predicting success have been identified. These are performance parameters such as grades from the secondary school graduation certificate, scores from ability and knowledge tests, as well as personality parameters (Rindermann & Oubaid, 1999).

The highest predictive strength as a single predictor has been attributed to the grade from the secondary school graduation certificate (*Abitur*), which is a measure for the general domain-*un*specific study ability. Likewise, pre-knowledge has been intensively surveyed, usually by achievement tests. Its predictive strength is less than that of the final school grade, but increases with rising consistency of test and study content (Heine et al., 2006). Furthermore, abilities in deductive thinking are seen as central factors in measuring cognitive abilities, which show medium or satisfactory predictive strength (Heine et al., 2006). Ambiguous information can be found for personality scales like interest. Some studies show no predictive strength (Gold & Souvignier, 2005) whereas others find it meaningful (Giesen et al., 1986). Concerning gender, there is also inconsistent information for university students (Taasoobshirazi & Carr, 2008; Legg, Legg & Greenbowe, 2001). However, self-evaluation of one's own abilities is seen as an important predictor (Giesen et al., 1986), and the course of study can also have an influence on the students' position because of the different structures and requirements given (Preuss-Lausitz & Sommerkorn, 1968).

The aim of this project is to find variables that predict student success at the end of the first semester in chemistry using binary logistic regression and combining variables concerning both performance and personality of students. Only in few studies has this approach been applied.

For this purpose, questionnaires that survey a variety of variables have been developed. It is assumed that the secondary school graduation certificate grade will have most predictive strength, that pre-knowledge and abilities in deductive thinking will have less predictive strength and that subject interest, self-evaluation of abilities in chemistry, gender and course of study will possibly have some influence on student success.

Success is determined by passing the final exam in general chemistry at the end of the first semester.

STUDY DESIGN

A pilot study investigating the qualification and attitudes students in chemistry bring to university has been conducted.

Participants

The students were surveyed at the very beginning of their studies in October 2010. A total number of 241 students of the subjects B.Sc. Chemistry, B.Sc. Water Science and also chemistry education students who all take General & Inorganic Chemistry have participated in this survey. Table 1 shows the number of students who took part in the survey divided by course of study.

Table 1. Participants divided by course of study.

	Beginning of 1st semester October 2010	
Course of study	Frequency	Rel. frequency
B. Sc. Chemistry	55	23 %
B. Sc. Water Science	71	30 %
Chem. teach. stud. (GG)[1]	74	31 %
Chem. teach. stud. (HR)[2]	40	17 %
No answer	1	0,4 %
Total	241	100 %

Female (50 %) and male (49 %) students are equally present in the sample (1 % gave no clear answer). There are differences concerning the students' year of receiving their secondary school graduation certificate (*Abitur*). Thirty-seven percent did their final exam just before starting their studies in 2010; 31 % one year before in 2009 and 24 % earlier than that (8 % gave no clear answer).

Material

The survey contains several questionnaires. *Personal data* were collected concerning facts like grade from the secondary school graduation certificate (*Abitur*) and other demographic data.
The *Chemistry Knowledge Test* is an achievement test consisting of multiple-choice items. All tasks deal with knowledge that is taught during the first semester in chemistry at university. A further item asks for a self-evaluation of one's own performance on this test by giving one's self school grades.
The *Test for Measuring Deductive Thinking* is taken from Wilhelm, Schroeders & Schipolowski (2009). It consists of a verbal, calculative, and visual part.
The *Self-evaluation Questionnaire* asks for self-assessing the own capabilities and knowledge relevant for taking chemistry courses.

> Example: I think I am capable of solving tasks on the topic of acids and bases.

The purpose of the *Questionnaire on Subject Interest* is to examine the amount of interest the students have in their subject.

> Example: I'm studying this subject because engagement in chemical topics and matters is important to me.

For responding to the questionnaires on self-evaluation and subject interest, a four-point Likert scale is given for specifying one's level of agreement. Among the self-constructed items, there are also a couple of proven and tested ones from literature (Jerusalem & Schwarzer, 1986; Schiefele et al., 1993) for validation reasons. Validity and reliability (using Cronbach's alpha) for both scales, self-evaluation and subject interest, could be proven.

[1] Chemistry teacher students for intensified general education and comprehensive schools
[2] Chemistry teacher students for basic and extensive general education

Additionally, scores on the final exams in chemistry at the end of the first semester have been gathered. Students of B.Sc. Chemistry and B.Sc. Water Science took the same exam whereas the teacher students took different exams. Due to this fact, only the results of Bachelor students were used in the following analysis.
Out of the 241 freshmen who took part in the first survey in October 2010, only 175 also took the final exam; 95 of them were B.Sc. Water Science and B.Sc. Chemistry students.

RESULTS

In comparison to linear regression, logistic regression enables one to predict category-dependent variables. In this study, the binary variable *student success* ought to be predicted. Binary variables usually have the two values "0" and "1". Therefore, a successful student is characterized by passing the final exam at the end of the first semester and is assigned the value "1", whereas a less successful student, who does not pass the final exam at the end of the first semester, is assigned the value "0".

With the help of logistic regression it is possible to calculate the probability for every student to belong to the group of successful students.
The calculation is done by including a couple of independent variables in a regression model. The relationship between the independent variables (predictors) and the dependent variable is not linear, but built by a logistic function.

After determining the independent variables that have an impact on success in chemistry, the regression model was calculated using SPSS.
The result of the binary logistic regression is shown in Table 2. The most important value to interpret is Exp(β), which is called odds ratio and is the factor by which the probability of belonging to the successful student group increases when the independent variables rise by one unit. For example, the odds to be in the group of the successful students are 1.157 times higher for a student having one point more on the chemistry knowledge test than another student when all values of the other variables are identical. The same is true for deductive thinking. A student having one point more on the test for measuring deducting thinking than another student is 1.282 times more likely to be successful.

Table 2. Result of binary logistic regression for predicting success.

	β	SE	Wald	df	Sig.	Exp(β)	95% conf. int. EXP(β) Lower value	Upper value
Knowl. Test[3]	0.145	0.077	3.575	1	.059	1.157	0.995	1.345
Vis. Ded. Th.[4]	0.248	0.093	7.177	1	.007	1.282	1.069	1.538
Final grade[5]	-0.482	0.243	3.918	1	.048	0.618	0.383	0.995
Study Course[6]	1.643	0.539	9.278	1	.002	5.169	1.796	14.873
Constant	-3.110	1.581	3.869	1	.049	0.045		

[3] Chemistry knowledge test
[4] Visual part of the test for measuring deductive thinking
[5] Grade in secondary school leaving certificate
[6] B. Sc. Water Science or B. Sc. Chemistry

One can therefore see that the course of study has the highest impact on study success since the probability increases by a factor of roughly five if the value of the course of study changes by one unit from zero to one, which means from a student being enrolled in B.Sc. Water Science to a student being enrolled in B.Sc. Chemistry.
Only for the grade from the secondary school graduation certificate (*Abitur*) do lower values reflect higher abilities. So if the grade is one unit higher – which means worse – the probability for success shrinks. It will be only 0.618 times as high.

Other variables like subject interest and self-evaluation of capabilities in chemistry as well as gender do not significantly improve the model.
However, with the help of the regression model, it is possible to correctly assign 77.7 % of the students into the groups of successful and less successful students, respectively.

DISCUSSION

The best single predictor for success is pre-knowledge. This finding contradicts existing literature since the grade from the secondary school graduation certificate (*Abitur*) is usually thought of as the best single predictor for success. Attending a chemistry course in upper secondary school as a further aspect of pre-knowledge has not turned out to show any predictive strength. This could be possibly due to the fact that its influence depends on how far courses in school chemistry date back and if subject related work experience exists.
Concerning the ability in deductive thinking, the results only partly confirm the literature since only the visual part could be included in the regression model. However, this seems reasonable since studying chemistry requires the students to visualize concepts like atoms or orbitals and to think three-dimensionally. For subject interest and gender, ambiguous information can be found in the literature and, in this project, results show predictive strength for neither of them. The same can be found for self-evaluation.
In contrast to this, the course of study has a large impact on student success. This finding can be explained by the different structures of both courses of study. An important aspect is the fact that only B.Sc. Chemistry students have had a laboratory internship before taking the final exam at the end of the first semester. So B.Sc. Water Science students missed some important learning opportunities to deepen their knowledge in chemistry.

Outlook

The survey will be repeated at several German universities and also one in Finland in winter semester 2011/12. One can expect that students from different study locations will differ from each other.
With the help of the data, a general picture of freshmen in chemistry can be established and based on this, types of students can be identified with the help of cluster analysis. According to their initial qualifications those types can then be supported adequately to raise success rates in chemistry.

PROFESSORS' PERSPECTIVES ON DROPOUT RATES IN UNDERGRADUATE PHYSICS COURSES

Paulo Lima Junior, Fernanda Ostermann and Flavia Rezende
[1]Universidade Federal do Rio Grande do Sul (Brasil)
[2]Universidade Federal do Rio de Janeiro (Brasil)

Abstract: This paper reports an analysis of a focus group composed by Physics professors at the Federal University of Rio Grande do Sul, in Brazil. Professorial discourse was analyzed and contrasted to Bourdieu's sociology of education aiming to apprehend professorial standpoints concerning dropout rates in the Physics course, which are the highest in the country. Under the professors' perspective, students decide to dropout Physics undergraduate course mostly due to having formative deficiencies or not having the proper vocation. When they came to consider social variables, they perceive dropout as strictly related to economical distribution. In this sense, they believe inequity and drop out of the less prepared could be avoided by institutional actions as scholarship programs. On the other hand, when they describe pedagogical actions they could implement to reverse dropout, they assume responsibility for the problem. In this perspective, professors seemed to be not aware on the role the whole educational system plays in social and cultural reproduction of ruling classes. We believe that the access to Bourdieu's framework may lead professors to a sociological understanding of education and particularly of undergraduate Physics and, thus, to conceive more critical proposals for Physics teaching.

Keywords: Sociology of Education, Dropout Rates, Undergraduate Physics

BACKGROUND

Massive dropout in undergraduate Physics courses is a phenomenon that affects higher education institutions worldwide. This paper reports a research that constitutes a wider project aiming to investigate the reasons of dropout in Physics' undergraduate courses and its relation to quality of Physics teaching. An Institute of Physics (IP) under a federal Brazilian university was chosen as the case of study.

Indeed, Physics is amid the undergraduate courses that hold the highest dropout rates across this country (Silva Filho et al., 2007). Though dropout is a traditional theme in educational research, it has not yet been understood why are dropout rates higher in Physics' undergraduate courses and how these dropout rates are related to teaching.

In Brazil, recent changes in educational politics have brought dropout back to discussion in the national arena. In 2007, the government instituted a national program for higher education called Reuni[1]. This new national program has offered pecuniary benefits, scholarships, and professorial positions for the universities that committed to expand students' vacancy and to raise graduation rates. Together, these goals imply controlling dropout.

[1] Acronym that stands for "Program to support the restructuring and expansion of federal universities".

FRAMEWORK AND PURPOSE

The theoretical framework adopted for this paper is Pierre Bourdieu's Sociology of Education. Without the ambition of summarizing every contribution this author brings to the understanding of sociological issues in education and science education, it is possible to highlight several *theses* (Bourdieu, Passeron, 2009):

- **Competition in school.** Students do not compete under the same conditions in the educational system, not only because there are poor and rich families, but mostly because different families own different amounts of cultural capital.
- **Definition of cultural capital.** Cultural capital comprehend a variety of non-pecuniary features that make one's family more or less cultivated (such as scholar grades, mastery of cultivated language, information about the "scholar world", knowledge on sciences and other school subject matters).
- **The main role of school.** Despite being relatively independent of issues such as class struggle, the educational system has the main role of inculcating the culture of culturally ruling classes (eg., through its selection of curricular content matters and assessment methods);
- **Scholar contribution to social reproduction.** A straightforward implication of drawing its practices from the culture of culturally ruling classes in an heterogeneous society (concerning the distribution of cultural capital) is that school contributes to the greater success of students that stem from families that own more cultural capital due to the various advantages of being raised in a more "educated" environment.
- **Education and dissimulation of power.** It is fundamental for any teaching practice that aims to reach legitimacy that it conceives the relation of power lying beneath the definition of what should be taught and on which basis should students be assessed; The most successful is the school in conceiving the arbitrariness of the culture it inculcates, the most school legitimates this culture as dominant and their owners as culturally ruling class.

Hence, the condition of culturally ruling class is likely to be reproduced from one generation to another. Together, these *theses* express how school contributes to the social reproduction of culturally ruling classes and how class reproduction constitutes students' life in the educational system.

Considering the consistency of these *theses*, even if the same education is given to every student from the first day in school and even if assessment is "neutral", there will not be equal opportunities to every student as long as their families hold different amounts of cultural capital. Indeed, Bourdieu's sociology of education brings very critical perspective to the ideas that scholar success is related to individual gift, merit or vocation and to the idea that expanding the access to education is a solution to class struggle.

Given Bourdieu's framework, the purpose of this study is to analyze professorial discourse concerning dropout in a Brazilian undergraduate Physics course. For example, we will give attention to what causes they attribute to dropout, if they are social or individual and what would be the role of university to solve the problem.

METHODS

For this research, a focus group (Gatti, 2005), which is a technique for collecting verbal data from group discussions, was used. The discussion has involved 8 professors that were randomly chosen from faculty. There was also a mediator who was responsible to engender discussion through means of previously prepared open ended questions concerning teaching and dropout in undergraduate Physics course. The focus group was recorded in audio and video. The analytical device developed for this record was drawn from Bakhtin's social theory of language (1981, 1996) which is consistent to the theoretical grounds of Bourdieu's sociology of education (Hanks, 2008).

For Bakhtin and his colleagues, language is fundamentally a social phenomenon. He asserts that the *utterance* (complete speech act), in contrast to words and phrases, is the actual unity through means of which language is realized in human life (Bakhtin, 1996). As a matter of fact, the utterance has several distinguishable features such as *responsivity* and *directionality*. Each utterance is responsible for it agrees, contends or completes other utterances. Besides, every utterance is directional since it is likely to incite new utterances (the listener is another speaker) and it cannot escape the influences of anticipating these responses. This analytical device consists mainly of a procedure of analyzing responsive and directional relations between professors' speech acts.

The analytical device may be distinguished into three stages: (1) Narrative board; (2) Genetic diagrams; (3) Synthesis of the debate. The so called *narrative board* is essentially an ensemble of transcriptions and descriptions that represents verbal (and non verbal) actions taken in the focus group. Besides reducing the time necessary to fully transcribe the whole registers, this narrative board leads to a more straightforward understanding of what is on stake though the debate. From this narrative board, it was possible to observe the subthemes around which professors gravitate. For each of these themes, professors' utterances were organized in the so called *genetic diagrams*, which are representations of how research subject collectively develop new perspectives in a debate through means of agreeing, contending and expanding other's ideas. These discursive movements were respectively categorized under the bakhtinian concepts of ventriloquism, resistance and appropriation. Finally, from the genetic diagrams it was possible to observe, amid the various perspectives professors brought to the debate, that some standpoints are shared between (most) group members. These are presented as results of the analytical device.

ANALYSIS

As an example of how the analytical device has been implemented, we present here some excerpts of the narrative board along with its respective genetic diagram. As the narrative board involves both descriptions and transcriptions, it is important to highlight that literal transcriptions are always presented between quotation marks:

Mediator: The mediator, concerning undergraduate Physics courses, asks "What do you consider a Physics course of quality?".

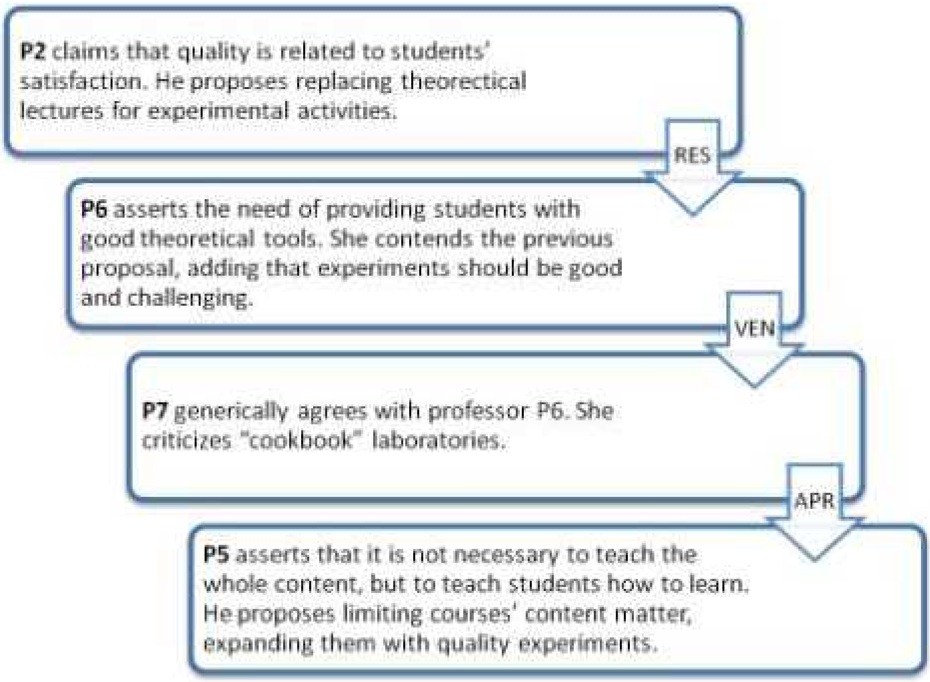
Prof_2: This professor claims that the quality of a Physics course is related to students' satisfaction. He says the course should be improved by means of planting interesting experiments. In reference to a specific discipline, which has gone through a large curricular reform some years ago, this professor declares that, in the period prior to the reform, "the student once a week, entered the laboratory, where there was a lot of experiments. It was not a single experiment. [...] Nowadays, students come to class and teachers spend 45 minutes lecturing! That would be an opportunity to improve this teaching, to make this more attractive to students, replacing the 45 minutes of lecturing for more experiments". Finally, this professor claims for radically replacing theoretical lectures for experimental activities.

Prof_6: This professor emphasizes that one needs to basically master theoretical foundations. She said "there's no way to learn physics only through experiments. From my point of view, one needs to organize their ideas. It is necessary to systematically teach concepts." Finally, she adds that the experiments must be good and challenging.

Prof_7: This professor says to agree to every word of Prof_6. She criticizes those "cookbook" laboratory activities. She repeats some of the claims make by Prof_6 in agreement.

Prof_5: This professor claims that Physics' curriculum does not need to embrace every content matter traditionally ascribed to undergraduate Physics course. On the other hand, curriculum must scaffold students to find their own way around. This professor says: "I think that we could be more selective on content matter and provide students with fewer but good bibliography, with interesting and advanced experiments with good theory. I have already noticed that there are things that I did not know by the end of my undergraduate course. However, as I've had a consistent education, I was capable of learning almost by myself. Then, I think that we need to limit content matter and add high quality experiments". Finally, this professor claims that a course of quality should teach students' how to learn.

Figure 1. Genetic diagram for the subtheme "experiments and the quality of Physics' undergraduate course".



Despite the differences between the perspectives every professor brings to the debate, it is possible to observe from this diagram how these perspectives are responsively related to each other. Hence, the genetic diagram is likely to clarify the relations (of ventriloquism, resistance and appropriation) between the various utterances that approach each subtheme. From this diagram, it is possible to observe that the last standpoint presented is an actual *synthesis* of conflictive perspectives brought by previous utterances. Finally, this analytical device was applied to every subtheme that arose in the debate. Results presented are the syntheses professors' standpoints.

RESULTS

From the analysis, it is possible to claim that professors' standpoints concerning dropout and quality in Physics teaching are the following:

- **Merit, vocation and formative deficiencies.** Under the professors' perspective, students decide to dropout Physics' undergraduate course mostly due to having formative deficiencies or not having the proper vocation.
- **Income distribution: THE social factor.** When professors approached social variables related to school success, they evoked income distribution, which has not been considered an educational issue since the formative deficiencies that poor students are more likely to have were considered to be surpassed only through means of scholarship programs.

- **Standpoint concerning REUNI.** REUNI is considered by professors an artificial and false solution to a very complex problem: the relation between student's class condition and access to and permanence in higher education.
- **The institutional role in controlling dropout.** Professors considered that, despite the lack of vocation and formative deficiencies students are likely to have, it is possible to slightly reduce dropout rates through means of giving more exciting classes, exploring interesting classical phenomena, new findings and technologies related to Physics.

It is important to highlight that professors' proposals did not take into account that giving the same education to socially different students means *not* to give them the same opportunities. After a long discussion about what are not their duties and responsibilities concerning students, professors approached what they actually could do about teaching so as to foster students' success and permanence in undergraduate Physics course. Under their perspective, the major contribution would be giving more exciting classes through means of exploring interesting classical phenomena or bringing to class new findings in the fields of Physics and its technologies.

CONCLUSIONS AND IMPLICATIONS

Professors frequently separated social issues (which were considered mainly economical) from the educational issues of lecturing and assessing students. Once this demarcation is established (once it is agreed that social issues, such as formative deficiencies ascribed to lack of economical capital, should not be of professorial concern) they feel comfortable to propose new pedagogical practices that might reduce dropout.

As it is possible to observe, this strategy of separating social from educational is immediately related to the merit, gift and vocation ideologies (for which Bourdieu brings critical perspective). More than a simple lack of awareness (Physics' professors not knowing Bourdieu's sociology), the separation social-educational protects the legitimacy of educational practices in the undergraduate Physics course from a more fundamental attack: from being accused of contributing to the reproduction of social class structure.

DETERMINANTS AND FINALITIES IN THE CHOICE OF REVIEWING PROCEDURES: THE CASE OF RDST, A FRENCH SCIENCE EDUCATION RESEARCH JOURNAL

Ludovic Morge
Clermont Université, Université Blaise Pascal, IUFM d'Auvergne, France
Laboratoire ACTé (EA, 4281)

CS. 20001
63407 Chamalières Cedex

Abstract: The merging of two French journals both publishing articles on research in science and technology education has made it necessary for them to compare the different reviewing procedures used by each. This comparison highlights two points: first, there are extrinsic and intrinsic determinants which affect the choice of reviewing modalities; and secondly, there are two finalities which could lead to the two journals converging, namely, the equity (fairness) or the equality of the different reviewing procedures.

Keywords: reviewing procedures ; journals ; science and technology education ; researcher ; community.

THE QUESTIONS RAISED BY THE MERGING OF THE TWO JOURNALS

Recherches en Didactique des Sciences et des Technologies is a very recent journal. The first issue was published in June 2010. This new francophone journal was the result of merging two French journals *Aster* and *Didaskalia*. These journals differed in several ways.

First, they did not have the same sections. *Aster* is a thematic journal, whereas *Didaskalia* is essentially non-thematic, even though some issues do contain articles on the same theme. *Aster* only contained research articles, whereas *Didaskalia* had other sections (such as points of view, reports on innovations, and reading notes). Thematic articles were reviewed at fixed dates, whereas the times at which non-thematic articles were reviewed could vary considerably.

Reviewers were not selected in the same way. The selection of the reviewers is an important phase of the reviewing procedure (Street et al, 1998). *Aster* systematically asked for two reviews, and a third if there was disagreement. However, *Didaskalia* always had three. For *Aster*, reviewers were selected by an editorial committee, which was made up of about 10 researchers from different French laboratories. One of the members of this committee was appointed specifically to supervise corrections to the article. For *Didaskalia*, it was the chief editor who selected the three reviewers.

Reviewing procedures also were different. For *Didaskalia*, it was the reviewers who studied the revised version of the article and decided whether the author had followed their recommendations. For *Aster*, it was the member of the committee who had been appointed to supervise the modifications who decided, together with the editorial committee, on the quality of the second version, and whether the author had followed the recommendations. For *Didaskalia*, the journals themselves were sent to the authors. For *Aster*, the committee member supervising the work wote a summary of the journal, and sent it to the author.

The grids designed for reviewing also differed. The *Aster* reviewers were sent a text describing the reviewing procedure, which provided some general indications (such as the intrinsic coherence, the logical organization of the arguments, validity of the method, theoretical references). The *Didaskalia* reviewers were sent a grid to be filled in with different sections (the presentation of the arguments, the theoretical framework, methodology, findings, discussion and conclusion, and the coherence between the different parts…).

To sum up, we can thus see that even if the two journals both published articles on research in science and technology education, eve, if they use the double blind peer review process (Baker, 2002), they did not use the same reviewing procedures. The new journal, RDST, kept all the sections from both *Didaskalia* and *Aster*. When the two journals merged, it was decided that, to begin with, the two reviewing systems would coexist, so that the first issue of RDST could be brought out on time. Afterwards, the editorial committee began studying ways in which the two reviewing procedures could converge. This discussion took place in a specific context.

THE RESEARCHERS' PROFESSIONAL MILIEU

The pressure of evaluation on university researchers was increasing considerably in France at the time of the merger of the two journals. The main criterion for evaluating research activity became publishing articles in international journals with an editorial board. Because of this, the need for all authors to have equal chances has become much greater.
The fact that it is now more important to consider this equality of opportunity has several consequences. For example it calls into question the idea that the complementarity of articles on a given theme (which is a criterion determined in the readers' interest) should be one of the criteria for choosing an article in the thematic section. It also calls into question the fact that the themes should be defined by the editorial committee alone. This also makes it necessary to harmonize reviewing procedures for the new journal, whether the articles are submitted for the thematic or the non-thematic sections.

HARMONIZING REVIEWING PROCEDURES

The ways in which harmonization has already been achieved

Two reviewers are selected for each article submitted to RDST. A third reviewer can be called on if there is any disagreement. This compromise has been established so that the procedure is not too far from international standards (3 reviewers), whilst taking into account the fact that there are fewer French-speaking reviewers than English-speaking ones.
The second way in which reviewing procedures have been harmonized concerns the supervision of modifications (the selection of reviewers, analysis of the reports, and expression of an opinion concerning possible publication of the article). While this work was done only by the chief editor for *Didaskalia*, it seemed preferable for there to be different points of view on these three points which are so crucial in reviewing.
For the non-thematic articles in RDST, supervision is carried out now by a chief editor who is in charge of the non-thematic section, and also by a member of the editorial committee. As for the thematic articles this task is given, as it was for *Aster*, to a member of the editorial committee who takes into account the opinions of all the members of the editorial committee. Thus, as far as these three crucial points are concerned, articles in the thematic and non-thematic sections are treated more fairly, but not in the same way.

The harmonizing yet to be done

For the time being, the tools used for reviewing are not at all similar. For the articles in the thematic section of RDST, the reviewing tool could be seen simply as a guide for reviewers. For the articles in the non-thematic section, there is a reviewing grid. These tools have totally different characteristics. The grid makes it easier to compare different reviews with each other. On the contrary, the guide is less clear, and leaves more room for reviewers' personal expression (Castro et al. 2003), which makes it harder to compare reviews.
But on the other hand, it is harder to adapt the grid to different types of article, (e.g., for qualitative or quantitative research) (Santiago-Delefosse, 2003). In other words, the guide is an egalitarian tool (as the same guide is used for any research article), but it may cause the reviews to be less equitable as they tend to be based on more personal criteria. However, the reviewing grid, which needs to be different in order for it to be adapted to different types of article, is not an egalitarian tool, but means that reviews are more equitable.
If new reviewers are to be trained, and also if the reviewing procedure is to be more transparent, it would seem preferable to give all the reviews to each reviewer. Although several members of the editorial committee agree to this, there is not enough time for it to be done. This systematic exchanging of reviews (Piolat et Vauclair, 2004) would only be possible if an electronic system were used for the submission and management of articles.
The principle of authors remaining anonymous is respected in both the thematic and non-thematic sections. If it is not possible to consider doing away with this (as is the case in "Education Research in Mathematics") because of the limited number of French-speaking reviewers, anonymity could be reinforced by asking authors to replace their names by the word 'author' in the quotations and bibliographical references.
Finally, the difference in the way reviewing is processed (either sending the writer the actual reviews or sending them a summary of the reviews written by a member of the editorial committee) has not yet been tackled, and the two systems co-exist. What is at stake here is the participation of the editorial committee in the reviewing procedure.

CONCLUSIONS

The reviewing modalities for RDST are evolving towards a more equitable treatment of research articles (thematic or not), yet without these being identical. The analysis that has been carried out in this article has enabled us to determine three extrinsic factors which influence the choice of reviewing procedures for RDST: the authors' professional milieu (in this case, the way their research is evaluated), the number of French-speaking researchers, and lastly, the readers). The times at which reviewing is done (strict deadlines for thematic articles whereas this is not the case for non-thematic articles) is a factor which is intrinsic to the way a review functions, and has a considerable impact on reviewing procedures. In order for reviewing procedures to become identical in this review, the times at which reviewing is carried out will have to be changed.

GENDER DIFFERENCES IN 15 YEAR-OLDS' PERCEPTIONS OF PHYSICS, PHYSICS LESSONS AND PHYSICS TEACHERS.

Tamjid Mujtaba[1] *and Michael J. Reiss*[1]

[1]Institute of Education, University of London, London, UK

Abstract: This paper is based on quantitative survey findings of year 10 (15 year-old) students in 140 schools drawn from a longitudinal mixed methods project: Understanding Participation rates in post-16 Mathematics and Physics (UPMAP). The low number of students continuing with physics after compulsory education is a key concern amongst UK policy makers; the likelihood of girls going on to do physics post-16 is substantially less than that for boys despite there being no inherent gender difference in aptitude for physics. A literature review in conjunction with the team's expertise informed the development of a survey to explore students' attitudes towards various physics-related issues, support they received in physics learning as well as intentions to continue with physics post-16. Confirmatory factor analysis supported the various components of the survey, with some minor modifications. Analysis of the students' responses indicated the importance of teachers' encouragement in post-16 studies and further cemented our ideas about the importance of physics material gain motivation in inspiring students to continue on with physics after compulsory education.

Keywords: physics, gender, motivation, perceptions, teachers

INTRODUCTION

There are concerns around the gender gap in the uptake of post-16 physics in the UK as in a number of other countries in Europe and elsewhere; in addition, the gender gap is a continuous and established problem at secondary school, further education and higher education levels. Post-16 academic courses mostly take the form of Advanced Level (A-Level) in about two to four subjects with a great deal of student choice with examinations taken at age 18. In order to do physics at A-Level, students in the UK are typically required to get a high grade (A*, A or B) in the science or physics examinations they take at age 15 or 16. Attainment levels of boys and girls in physics/science at age 16 are quite similar with, if anything, girls doing slightly better (JCQ, 2011a). This demonstrates there is little if any inherent difference between boys and girls in their ability at physics.

In 2010, 51% of science General Certificate of Secondary Examination (GCSE) entries and 46% of these physics GCSE entries at age 16 were by girls. In contrast to this, the odds of girls going on to do physics post-16 are substantially less than that for boys, even after controlling for entry requirements into A-level, with the gender gap being wider for physics than for mathematics or any other science subject (JCQ, 2011b). The concerns with female participation rates in STEM (science, technology, engineering, mathematics) courses are also very much related to the high attrition rates of women at each post-16 stage as well as females in STEM careers (Blickenstaff, 2005). In the UK, there have been a number of national initiatives put in place to raise girls' engagement with physics by exposing them to educational activities that promote female-inclusive education such as 'Girls into Science and Technology' and 'Women into Science and Engineering'. These campaigns received much enthusiasm from schools (Smail et al., 1982; WISE, 2007). However, despite these initiatives, physics remains highly gendered. In response to this, the Institute of Physics commissioned a review with the hope that knowing what to do to boost girls' participation in physics A-Level would help resolve the problem with female recruitment into physics (Murphy and Whitelegg, 2006). However, the review was unable to come to firm conclusions about how to boost girls' participation in physics in post-compulsory education. Reasons put forward for the low participation of girls has ranged from: the low confidence and low science self-concept of girls, (Green et al. 2007); teacher influence and seeing the relevance of science (Reiss, 2004); lower levels of physics enjoyment and interest (Reid, 2003); and girls feeling STEM careers are for males (Lindsey et al., 1997).

CONTEXT AND METHODS

This paper is derived from the mixed methods longitudianal study Understanding Participation rates in post-16 Mathematics And Physics (UPMAP) study (2008-2011) which aims to identify factors that relate to students' intended choices with respect to physics and mathematics. This paper focuses on physics. We designed student questionnaires to include items from established psychological constructs alongside validated physics conceptual tasks. In total we had 5642 year 10 students who completed our surveys as learners of physics between October 2008 and April 2009. We also matched on data from the government such as prior attainment at age 11, gender, eligibility for free school meals (FSMs) and ethnicity.

The psychometric validity of our instruments were established via confirmatory factor analysis. Cronbach's alphas were used to assess the internal consistency of all constructs and these were found to have fair to high reliability (.6-.9). All of the items within each construct were scored so that a high score represents strong agreement (items were on a 6 point Likert scale), with scores above three indicate positive responses/agreements with statements. In this paper we explore students' perceptions, attitudes and motivations regarding physics lessons, physics teachers and physics itself. For such purposes we do not use the overall constructs but explore the importance of individual items within constructs. This focus was prompted by other UPMAP findings presented elsewhere suggesting there is more of a gender imbalance in perceptions, attitudes and motivations in physics than there is for mathematics. Previous work concluded that students' physics extrinsic motivation (i.e. students' intention to continue with physics because of the benefits they envisage for such things as job satisfaction and salary) was particularly important in encouraging year 10 students to continue with physics post-16 and the statistical significance of perceptions of teachers and lessons lost significance when controlling for students' physics extrinsic motivation.

RESULTS

For this paper the use of t-tests helped to gain an insight into the sorts of areas (perceptions of teachers, lessons and physics itself) that would be important for our work and inform the multi-level model analysis. The relationship between intention to participate and gender is consistent with general patterns of participation as reported in many studies. We found 13.3% of boys strongly agreed to continue with physics post-16 compared to 4.5% of girls while 17.7% of boys strongly disagreed to continue with physics compared to 24.9% of girls.

There were three areas that explored issues with teachers: encouragement, relationships and competence. Students on the whole had positive perceptions of their teacherse. Table 1 shows students were most positive about their teachers really wanting students to understand physics (mean of 4.93), followed by teachers believing that all students can learn physics (mean of 4.90). Students were least positive about teachers being interested in them as people (3.32) and physics teachers liking all students (mean 3.79). All of the items are summarised in Table 1 which includes the breakdown by gender and whether differences were statistically significant.

Table 1: Year 10 students' perceptions of physics teachers

Overall perceptions of physics teachers	All students			Boys			Girls		
Item	**N**	**M**	**SD**	**N**	**M**	**SD**	**N**	**M**	**SD**
**My teacher thinks that I should continue with physics post-16	2607	4.06	1.6	1253	4.33	1.49	1343	3.79	1.65
**I like my physics teacher	4878	4.02	1.54	2234	4.07	1.54	2625	3.99	1.51
**My teacher has high expectations of what students can learn	4448	4.82	1.07	2037	4.90	1.07	2395	4.76	1.06
My teacher believes that all students can learn physics	4423	4.90	1.03	2032	4.91	1.05	2373	4.89	1.01
My teacher wants us to really understand physics	4555	4.93	1.02	2088	4.96	1.04	2451	4.90	1.01
My physics teacher sets us homework	4715	4.79	1.24	2146	4.80	1.25	2552	4.77	1.23
My teacher believes that mistakes are OK when learning	4420	4.59	1.24	2048	4.57	1.27	2356	4.61	1.25
**My teacher is interested in me as a person	3704	3.32	1.56	1698	3.41	1.58	1990	3.23	1.53
My teacher seems to like all the students	4319	3.79	1.57	1969	3.79	1.59	2336	3.79	1.55
My teacher is interested in what students think	4434	4.26	1.36	2021	4.30	1.37	2396	4.23	1.34
My teacher only cares about students who get good marks	4347	4.38	1.44	1968	4.35	1.5	2363	4.41	1.4
My teacher lets us get away with not doing homework	4526	4.56	1.39	2061	4.56	1.44	2447	4.56	1.35
My teacher treats all students the same regardless of their ability	4439	4.36	1.39	2041	4.37	1.41	2382	4.35	1.37
**My teacher is good at explaining physics	4630	4.28	1.41	2119	4.47	1.36	2494	4.12	1.43
*My teacher marks and returns homework quickly	4346	4.05	1.47	1984	4.12	1.45	2344	3.99	1.49

Notes: ** significant at .001; * significant at .01; N (number); M (mean); SD (standard deviation); comparisons between girls and boys.

Teachers' encouragement: Boys were more likely to give positive responses about feeling their teachers: encouraged them to continue with physics post-16 ($t=8.085$, $p<.001$); had high expectations of what students can learn ($t=4.353$, $p<.001$).
Personal relationships with physics teachers: Boys were more likely to report their physics teachers were in interested in them as people ($t=3.426$, $p<.001$).
Competence of physics teachers: Boys were more likely to report that their physics teachers: were good at explaining physics ($t=8.328$, $p<.001$); marked and returned homework quickly ($t=2.918$, $p<.01$).

Students' perceptions of physics lessons

There were four areas that explored issues with physics lessons: laboratory and practical work; learning physics concepts; enjoyment of physics lessons; self concept in physics as impacted by physics lessons. All of the items are summarised in Table 2 which includes the breakdown by gender and whether differences were statistically significant.

Table 2: Year 10 students' perceptions of physics lessons

**Thinking about your physics lessons, how do you feel you compare with the others in your group?	4867	3.32	1.09	2233	3.63	1.08	2616	3.05	1.03

Notes: ** significant at .001; * significant at .01; N (number); M (mean); SD (standard deviation); comparisons between girls and boys.

Descriptive statistics indicated that students on the whole had positive perceptions of their physics lessons but with some areas of concern. Students were most positive about not being upset when doing physics (mean of 5.02), followed by looking forward to spending time in the laboratory doing experiments (mean of 4.11). Students were least positive about looking forward to physics classes (3.13) and not being bored when doing physics (mean 3.18), an indication that students were showing signs of being bored, closely followed by students reporting that they always knew what they were doing when doing physics (3.19). For some of the items in Table 2 there were statistically significant differences in responses between boys and girls, with boys reporting more positively about questions around physics lessons. The largest significant difference in responses between boys and girls was 'When I am doing physics I always know what I am doing' (.69 mean difference), followed by 'I do well in physics tests' with a mean difference of .62.

Laboratory and practical work: Boys were more positive about: looking forward to spending time in the laboratory doing practical investigations ($t=13.236$, $p<.001$); having the opportunities to do investigations to test out their own ideas ($t=2.435$, $p<.001$).
Learning physics concepts: Boys were: more likely to report that their teacher explained how physics ideas can be applied to a number of different situations ($t=9.630$, $p<.001$); more positive about having the opportunity to discuss their ideas about physics ($t=7.110$, $p<.001$); more likely to report seeing the relevance of physics lessons ($t=11.050$, $p<.001$).
Enjoyment of physics lessons: Boys were more likely to report: looking forward to their physics classes ($t=12.334$, $p<.001$); enjoying their physics lessons ($t=13.154$, $p<.001$).
Self concept in physics as impacted by physics lessons: Boys were: more positive about doing well in their physics tests ($t=16.670$, $p<.001$); more likely to report doing better in their physics lessons than their peers ($t=19.102$, $p<.001$).

Students' perceptions of physics

There were six areas that explored perceptions of physics: laboratory and practical work; usefulness of physics; self concept in physics; liking of physics; physics and social skills; and doing physics. Descriptive statistics (Table 3) indicated that students' responses about physics were generally positive though there were some aspects of physics that students were not positive about / did not agree with. Students were most positive about / in agreement with 'To be good at physics, you need to work hard' (mean 4.66) and least positive about 'Being good at physics makes you popular' (mean 1.95).

Table 3: Year 10 students' perceptions of physics

Perceptions of lessons	**All students**			**Boys**			**Girls**		
Item	**N**	**M**	**SD**	**N**	**M**	**SD**	**N**	**M**	**SD**
**I think physics is a useful subject	4988	4.24	1.24	2292	4.43	1.24	2676	4.08	1.21
**I think physics is an interesting subject	4904	3.67	1.45	2246	3.99	1.45	2641	3.40	1.40
**I think physics will help me in the job I want to do in the future	4868	3.05	1.59	2235	3.35	1.65	2615	2.80	1.50
**I am good at physics	4880	3.84	1.31	2254	4.23	1.21	2606	3.49	1.28
**People who are good at physics get well-paid jobs	3820	4.17	1.18	1776	4.28	1.1	2028	4.07	1.17

Being good at physics impresses people	4187	3.36	1.41	1889	3.40	1.44	2287	3.33	1.38
**Physics teaches you to think logically	4400	4.05	1.25	2020	4.15	1.29	2364	3.96	1.21
**Physics helps you in solving everyday problems	4484	3.33	1.30	2062	3.47	1.37	2409	3.21	1.28
Physics improves your social skills	4361	2.20	1.21	1965	2.27	1.30	2382	2.13	1.12
**To be good at physics, you need to be creative	4397	2.57	1.31	1987	2.84	1.41	2398	2.35	1.17
To be good at physics, you need to work hard	4712	4.66	1.22	2138	4.69	1.22	2560	4.64	1.22
**Being good at physics makes you popular	4225	1.95	1.17	1909	2.08	1.23	2305	1.84	1.06
**Physics is interesting	4920	3.60	1.53	2251	3.92	1.53	2653	3.32	1.48
**Physics is important in making new discoveries	4576	4.57	1.22	2110	4.67	1.21	2450	4.48	1.23
**Those who are good at physics are clever	4435	4.06	1.40	2023	4.14	1.38	2398	4.00	1.41
**These days, everybody needs to know some physics	4498	3.95	1.27	2062	3.99	1.31	2422	3.91	1.23
**It's interesting to find out about the laws that explain different phenomena	3719	3.90	1.45	1777	4.12	1.41	1934	3.70	1.46
**There is only one right way to solve any physics problem	3489	4.23	1.38	1655	4.17	1.46	1824	4.28	1.29
**I don't need help with physics	4900	3.37	1.52	2243	3.82	1.53	2639	2.99	1.40

Notes: ** significant at .001; * significant at .01; N (number); M (mean); SD (standard deviation) ; comparisons between girls and boys.

For some of the items in Table 3 there were statistically significant differences in responses between boys and girls, with boys reporting more positively about questions around physics. *Usefulness of physics:* Boys were more likely to report that: physics is a useful subject ($t=10.021$, $p<.001$); physics is more likely to to help them get into jobs they want to do in the future ($t=12.196$, $p<.001$); physics teaches individuals to think logically ($t=5.270$, $p<.001$); physics helps individuals to solve everyday problems ($t=6.697$, $p<.001$); physics is important in making new discoveries ($t=5.243$, $p<.001$); people who are good at physics get well paid jobs, ($t=5.655$, $p<.001$).
Self concept in physics: Boys were more likely to report that they: are good at physics ($t=20.625$, $p<.001$); do not need help with physics, ($t=19.821$, $p<.001$).
Liking of physics: Boys were more likely to report that: physics was an interesting subject ($t=14.372$, $p<.001$); they found physics interesting ($t=13.753$, $p<.001$); these days everyone needs to know some physics ($t=2.102$, $p<.05$); it is interesting to find out about the laws of physics that explain different phenomena ($t=8.915$, $p<.001$); physics is a useful subject ($t=10.021$, $p<.001$).
Physics and social skills: Boys were more likely to report that physics: improves individuals social skills ($t=3.682$, $p<.001$); makes individuals popular ($t=6.671$, $p<.001$).
Doing physics: Boys were more likely to report that: to be good at physics individuals need to be creative ($t=12.508$, $p<.001$); those who were good at physics were those who were clever, ($t=3.379$, $p<.001$). Interestingly, girls were more likely to report that there is only one right way to solve any physics problem ($t= -2.275$, $p<.01$), which if read carefully is in line with many of the findings around physics. Girls, as a group, feel disengaged with physics and this may be related to the way it is taught, with girls not feeling there are a range of ways to learn physics.

Multi-level models that explore the importance of students' perceptions in intended post-16 physics participation

Multi-level models were run in a series of stages which had particular theoretical relevance and in this paper we will present the final, best fit model (model 6) rather than models run prior to this (Table 4), though will mention in passing results emanating from earlier models that became redundant, in order to elucidate issues around how extrinsic material gain motivation (i.e. students' intention to continue with physics because of the benefits they envisage for such things as job satisfaction and salary) is important in explaining intended participation.

We first established a variance components model, which indicated that 6% of the variance in intention to participate scores was attributable to differences between schools whereas the vast majority of the variance in scores was attributable to differences between students. In model 1 we differentiated between students' year groups, so that we could compare the impact of gender (when introduced in model 2). The younger students (year 8, aged 12-13) were statistically significantly more likely to express an intention to continue with physics in post-compulsory education. Model 2 showed that the gender gap between girls and boys in their intentions to continue with physics post-16 were larger for year 10 students than for year 8 students. Such differences continued after adjusting for students' age 11 (key stage 2) prior attainment scores and current conceptual ability in physics (in model 3), suggesting that even after controlling for students' attainment levels, boys were more likely than girls to express an intention to continue with physics post-16.

In model 4, we introduced items that explored students' perceptions of their physics teachers and found that even after adjusting for prior attainment, age and gender the following items were significant: 'my teacher thinks I should continue to study physics after the age of sixteen', 'my physics teacher is good at explaining physics' and 'my physics teacher is interested in me as a person'. However, in the final model it was only the last of these items that remained significant after controlling for physics extrinsic material gain motivation. In model 5, we introduced items that tapped into perceptions of physics lessons. Enjoyment of physics lessons was the only item that had a significant influence on intended participation in the final model. Though we saw the influence of prior attainment lose significance, we note that the influence of gender remained important in the final model and that this influence was stronger in the year 10 cohort than in the year 8 cohort.

In model 6 (our final model) we explored the influence of the items that measured students' perceptions of physics and within this grouping the following items were found to have a significant influence on intended participation: 'I think physics is a useful subject'; 'I think physics is an interesting subject'; 'I think physics will help me in the job I want to do in the future'; 'I am good at physics'; and 'I don't need help with physics'. Table 4 shows that the majority of the items that explain intended participation are those to do with perceptions of physics rather than ones to do with perceptions of teachers or of lessons (because at this point the great majority of items that were significant in previous models lost significance or had a weaker influence). Although teachers' encouragement of students continuing with physics post-16 was an important predictor, as were items to do with self-concept and enjoyment of lessons, the influence of such measures was still not as strong as extrinsic material gain motivation. This indicates that while other factors are also important in shaping students' intentions to participate in physics post-16, physics extrinsic material gain motivation is the most important.

Table 4: Factors that shape intended participation amongst year 8 and year 10 students

Fixed effects	Coefficient	Standard error
Intercept	3.514	0.03278
Year 8 or 10	-0.28	0.03
Gender (female)	-0.13	0.00
My teacher thinks that I should continue with physics beyond my GCSEs.	0.11	0.01
I enjoy my physics lessons.	0.09	0.01
I think physics is a useful subject.	0.20	0.02
I think physics is an interesting subject.	0.14	0.02
I think physics will help me in the job I want to do in the future.	0.40	0.01

I am good at physics.	0.08	0.02
I need help with physics.	0.02	0.01
Random effects variance	0.269	0.056

CONCLUSIONS AND IMPLICATIONS

An item analysis rather than a construct analysis found support for the importance of extrinsic material gain motivation on intended participation in physics. In addition the analysis showed that amongst the perception of teachers items, teachers' belief in individual students continuing with physics post-16 is the most strongly associated item with intended participation. This item was a significant predictor in the final multi-level model even after controlling for physics extrinsic motivation. Other items within the 'perceptions of teachers' cluster that were somewhat important in intended participation were teachers being good at explaining physics and teachers taking an interest in students as people (for both boys and girls). The multi-level findings indicate that enjoyment of physics lessons (intrinsic value), seeing the relevance of physics (extrinsic value) and students feeling they do well in physics are related to intended participation. There is a strong influence of gender on intended physics participation and the gender gap in perceptions of teachers, lessons and physics increases as students get older. These findings point toward recommendations to continue to promote and fund interventions, initiatives and practices that take into account of and attempt to reduce gender differences.

SELF-DETERMINATION AS KEY FOR A CROSS-CULTURAL COMPUTER-BASED LEARNING ENVIRONMENT

Antonio E. Rueda Muñoz[1] and Manuela Welzel-Breuer[1]

[1]University of Education Heidelberg, Germany

Abstract: The overall aim of the investigation at hand is the insight into educational cross-cultural factors for implementing a specific computer-based learning environment (CBLE) abroad. In a previous study, this CBLE concerning optics for German science classes at secondary school level was developed and evaluated. For the cross-cultural explorative research, four Colombian schools were contacted. Their conditions (curriculum, computers available), the motivation of students working with the CBLE (n=284 divided in nine 8^{th}-10^{th} grade classes) and videotaped learning processes of some of these students (n=18) working with one unit have been studied. A statistical analysis of questionnaires dealing with external conditions and motivational issues has been conducted. A content analysis of videotapes, transcripts and answers to the exercises of the analyzed unit has been accomplished. Results show that students mostly worked with high discipline and against the intentions very teacher-centred. When talking, students express themselves abruptly. Conceptual contents were used less precisely. It has been interpreted that self-determination could be a crucial criterion for the successful adaptation of the CBLE over three different levels: (1) Colombian teachers didn't adapt the experimental CBLE to their curriculum, which thwarted the targeted work in classroom; (2) the CBLE itself demanded more autonomy than students experienced; and (3) if students were asked to determine their learning processes themselves, they had to verbalize their thoughts as much as possible. Therefore this explorative study shows that states of self-determination at these three levels should be considered prior to cross-cultural implementations of CBLEs.

Keywords: Self-determination, Cross-cultural, Computer-based, Motivation, Learning

INTRODUCTION

In times of commercial globalization, educational systems also experience a pressure to be universalized and harmonized (e.g. Sjøberg 2007). Some ethnographical studies have thrown some light on cultural diversity in science education (e. g., Mueller & Tippins 2010). Teachers are due to accommodate global aims of science instruction to the local situations and necessities, especially because of the rising opportunities of the information and communication technology (e.g., Parrish & Linder-VanBerschot 2010). For instance, Oliveira et al. have studied the adaptation and implementation of an US-American learning environment to the conditions of other countries made by local teachers (Oliveira et al. 2009). Some authors highlighted the challenges of increasing sensitivity to cultural differences, people's values and lifestyles (e.g., Rogers et al. 2007).

The present contribution is dedicated to possible indicators for the "culture-equitableness" of a computer-based learning environment. This learning environment was developed in Germany for science classes at secondary school level (Schnirch 2006). It deals with light phenomena (physics) and the perception of the human eye (biology) integrating real experiments. The overall question of the present study was the use of this computer-based learning platform in a different cultural context. For it, an explorative research has been conducted in Colombian schools, in which the *previous external conditions* of schools and science classes have been assessed, the *motivation* of students while working with the learning environment has been analyzed, and *learning processes* concerning one unit of the CBLE have been examined. These three levels are separately represented in the following chapters.

RATIONALE

The three introduced levels for the cross-cultural explorative investigation are based on different theoretical frameworks explained in brief as follows.

Concerning the Previous External Conditions of the Investigated Schools

Over the past years the Colombian Ministry of Education has developed a so called Revolution of Education, which is focussed on the evolution of educational covertures considering efficiency, coordination of territorial educational offers and the active implication of population (M.E. 2002, M.E. 2008b). Amongst others, pedagogical standards concerning competencies for science (and social) education have been represented as guide for local adaptation (M.E. 2004a, 2004b). Moreover, innovation and use of Information and Communication Technology (ICT) are part of a big programme that pursues updating of computer-labs, expansion of internet-connectivity, vocational training of teachers and establishment of an internet network containing multiple teaching and learning materials[1].

Self-Determination Theory of Motivation

Deci and Ryan (1985) developed the Self-Determination Theory of motivation (SDT), which declares that every form of human motivation goes back to the endeavour to fulfil basic and innate needs. Those basic needs are autonomy, competence feedback, and relatedness. By internalizing extrinsic motivation through self-determined motivation one can reach intrinsic motivation. This process is called internalization and refers to people’s “taking in” a value or regulation. As people internalize regulations and assimilate to the self, they experience greater autonomy in action. The extrinsic motivation is thereby divided in four different levels of regulation (external, introjected, identified and integrated) that defined the process of internalization of a given activity towards intrinsic motivated behaviours.

Linguistic framework for Analysis of Learning Processes in Verbalizations

The theoretical approach of the present study in terms of learning is based on constructivism (e.g. Glasersfeld 1995, Vygotskij 1978) and Luhmann’s social systemic theory (Luhmann 1984). A detailed theoretical analysis will be given in future publications. The present contribution deals with the analysis of verbalizations of students during autonomous work in science classes. For it, Bloor’s linguistic Strong Programme has been considered (Bloor 1980). Herein language is divided into three domains: (1) Physiological, psychological, biological intuitions and skills, (2) social interests and needs, and (3) language-games and meaning. The first domain is supposed to be related to the grammatical and syntactical structure of language (Chomsky 1972). Within this domain in the present investigation, deductive content analysis using Halliday’s Systemic Functional Grammar (Halliday 2004) has been conducted. The second and third domain are linked to interpretation of wording and context (Kertész 2004). These have been inductive qualitative analyzed (category-based) in the present explorative research.

RESEARCH METHODS

A brief introduction with respect to the research design precedes the research methods for better understanding of the whole research study.

Chronological Research Design

The data for the three analytical fields of the investigation (external conditions, motivation and learning) have been gained during two stays in Colombia (two weeks in October 2007 and four weeks in February-March 2008). The conditions within these schools with respect to science classes and to the use of computers have been asked by means of a written survey during the first stay. As consequence of this, minor changes were included in the units of the computer-based learning environment and the integrated real materials for its adoption in Colombian schools. In February 2008 the learning platform was firstly introduced to teachers. After that, students worked with the computer-based tasks autonomously (approx. one hour). The nine participating classes (8^{th}-10^{th} grades) are three classes of a mono-educative school and two classes in each of the other three co-educative schools. Finally, one day after the computer-based work, the experiences made were debriefed with the whole class.

Method for the Analysis of Previous External Conditions

The conditions mostly regarding the personal appreciation of the use of ICT at home and school were asked by means of an explorative written survey. N = 16 teachers and n = 222 students were reached. Questions for teachers were focussed on the personal use of ICT and the way of implementation in science classes (19 closed items and 8 open questions). Besides, a personal estimation about the means of ICT in science classes (21 closed and 3 open items) and on students' interest in science (2 open items). Finally, personal interest of teachers in ICT and the investigation were consulted (7 closed items). Content and frequency analysis of these questionnaires have been conducted.

Method for the Study of Motivation

During the debriefing of the unit, students filled in a questionnaire related principally to motivation while interacting with the learning environment during the second stay. A total of n = 284 students (206 girls and 78 boys) completely filled in the questionnaire: A multidimensional measurement device (McAuley et al. 1989) that has been developed and evaluated at the University of Rochester intending to assess participants' experience related to a target activity in laboratory experiments. The multidimensional measurement device, called "Intrinsic Motivation Inventory"[2] (IMI), contains a variable number of items according to the requirements, and comprehends seven subscales that rest upon the Self-Determination Theory of motivation (SDT). These subscales are "interest/enjoyment", "perceived competence", "perceived choice", "social relatedness", "value/usefulness", "pressure/tension", and "effort/importance". An additional open question with reference to the acceptance of the learning environment was included.

In the previous study in Germany (Schnirch 2006) the IMI-questionnaire was already adopted and contained 41 items using a 5.likert-scale (from "strongly agree" to "strongly disagree"). Therein, the factor loading was proven by means of reliability analysis. Subscales were reliable and could be fitted to normal distributions. The Spanish version of the questionnaire

[2] http://www.psych.rochester.edu/SDT/measures/IMI_description.php

was translated using the German one. The comprehensibility of the items was checked by experts.

Method for the Analysis of Learning Processes

N =18 students (4 girls', 1 boys' and 1 mixed dyads; 1 boys', 1 girls' triad) working on one unit of the learning environment were video-recorded. The unit concerns the "red-eyes'-phenomenon" and the parts and functions of the human eye. At the end of each exercise, students had to write down their conclusions into a textbox inside the program. These conclusions were saved for research.

Concerning the analysis, first of all, recorded activities of students have been categorized. From this first examination, scenes containing conceptual verbalizations have been selected (approx. 40 minutes of 8 hours of videotapes) for further detailed analyses. Transcripts of these verbalizations have been compiled and studied in two steps (first two steps below). The written responses by students after each exercise are the database for the third step of the investigation. Hence, the three domains introduced in the rationale have been analysed separately:

- 1st step: Research on language intuitions by means of a deductive, category-based analysis of verbalizations, which are related to the contents shown in the learning environment. A category system was developed based on the Systemic Functional Grammar (SFG). Therein the grammatical function of verbal, nominal and circumstantial phrases and words within utterances and conjunctions linking complex clauses has been examined.
- 2nd step: Research on interest and intentions by means of an inductive, category-based analysis of the immediate actions, which initiate the verbalizations concerning the contents. Therein each content-related verbalization was supposed to be initiated by a certain event (e.g., question, teacher, other students). Moreover, the initiative of the action (learning environment, teacher, student) and the interpersonal behaviour (individual, collective) have been recognized.
- 3rd step: Research on meaning of written answers using an inductive, category-based analysis. The conceptual topics included in the final answers of students have been categorized and put into conceptual generic groups.

RESULTS

Concerning the Previous External Conditions

The analysis of data collected during the first stay in the Colombian schools yielded that the implementation of the German learning environment in science classes could be conducted. Schools owned computer-labs (one or two labs à approx. 20 PCs for the whole school). In two of four schools equipments needed updating. On the one hand, teachers moderately used ICT for preparing their science classes. Some of them didn't implement ICT in science classes. Nevertheless, almost all teachers asked shared the opinion that teaching with ICT needs an adapted teaching methodology. They also highlighted the potentiality of ICT for educational purposes. Concerning the personal use of ICT, teachers draw on them for writing documents and virtual networking. A training session for teachers previous to the work with students was added to the research design. Nevertheless, teachers did not feel confident enough after this training session to implement the unit by themselves.

Concerning Motivational Aspects

The means of almost all subscales of the IMI measurement device were very high. From this point of view it could be concluded that students were intrinsically motivated while working with the learning environment. That is why small differences of means have been closely examined. The subscales “interest/enjoyment” and “value/usefulness” got the highest means. In contrast, “perceived choice”, “effort/importance” and “pressure/tension” showed slight differences to the other four subscales. An in-depth analysis of the data leads to the assumption that the answers were not normally distributed for which reason they presented high skewness. Moreover, it has been noticed that the wording of questions played an important role in answering. Distributions of negative worded items differed considerably from positive worded. The study of these features has been presented elsewhere (Rueda & Welzel-Breuer 2009).

Concerning Learning Processes

The recorded verbalizations of students while working with the unit that deals with the “red-eyes’-phenomenon” and the constitution of the human eye have been studied in two steps. The third step concerned the content analysis of written conclusions of students.

- 1st step about grammatical analysis: In most of the cases students talked very abruptly without following a marked argumentation pattern. They expressed their ideas in single word groups or incomplete clauses. By means of a category-system based on SFG the grammatical content of verbalizations of students has been examined. Determinative nominal groups (e.g., single nouns) and material verbs (e.g. describing what happened) were the most frequent components of verbalizations. Moreover, students spoke more actively when the exercise had to do with assumptions about circumstances or events (e.g., the “red-eyes’-phenomenon” or the similarities of humans’ eyes to animals’ eyes). Although students found information about specific terms (e.g. properties of light, or parts and functions of the eye), they did infrequently construct verbal relations with them (e.g. “the light is very fast”). Complex clauses (e.g., using conjunctions) have been detected in few cases, in which only contingency (e.g., “if… then…”) and causality (e.g. “because…”) were detected. Few analogies (e.g., “this is like…”) or relations to what occurred (e.g., “where…”, “when…”) were identified. These shortly presented results can be summarize such that students spoke mostly about concrete events (single unspecific nouns and material verbs) without refining their discourses. They seldom showed a need for expressing conceptualization or interconnected ideas.
- 2nd step about contextual analysis: In the second step, it has been sought a reason for behaviours presented in the first step. The initiator of the content-related verbalizations was examined (e.g., interest of students, teachers, or learning environment). The behaviour of the 8 recorded groups before talking has been coded using three categories: Initiator (e.g., task, materials, students’ interests), initiative (e.g., learning environment, teacher, students) and interpersonal behaviour (individual, collective). It could be determined a spectrum of actions presenting two extremes: extrinsic-driven, intrinsic-driven behaviour. In addition, the behaviour of individuals had an impact on co-operative work of groups. Students who worked very interested did so mostly alone. Students who were not very interested stayed together. In between, two more levels have been distinguished: First, when students in groups worked extrinsic-driven, doing the tasks individually on their own (“self-awareness”); and second, when students were sometimes interested in the exercises and worked always together (“perception of common value”). Recapitulating, four levels have been detected (external control, self-awareness, perception of value, internal control), which could be associated to the four levels of regulation within the Self-Determination Theory of motivation introduced in the rationale.
- 3rd step about semantic analysis: The written conclusions of students for each exercise of the video-recorded unit have been explored using content analysis. Inductive-driven

systems of categories for each exercise has been built and interpreted. The students invested more time in writing answers about assumptions. Summarizing, a working process can be recognized in the semantic category-based analysis of the written answers. Two of eight groups properly connected the parts and functions of human's eyes with the "red-eyes'-phenomenon". The other six groups didn't realize this connection or didn't write enough correct arguments. Therefore, it can be interpreted that these six groups didn't take control of their own learning processes.

CONCLUSIONS AND IMPLICATIONS

An explorative research of the implementation in Colombian schools of a German computer-based learning environment that includes real experiments has been conducted in small scale. The analysis has been divided in three parts: a macro-level (external conditions), a meso-level (motivation of students) and a micro-level (learning of students). One overall conclusion can be stressed from all three levels, namely, the importance of self-determination.

Although the heads of schools and teachers were very open-minded and helpful with regard to the implementation of the study, mainly teachers didn't integrate the unit in their science curriculum (in spite of consultation and arrangement before the second stay and training before adoption). This fact undermined self-determination and participation of teachers during the class-work and decreased concrete motivational value of the unit for students. Only slight differences in the results concerning motivation give reason to the interpretation that they couldn't work freely enough unfolding their self-determination during the autonomous learning. The role of the teacher is therefore to properly introduce such a computer-based unit encouraging autonomy of students. This interpretation has to be proven in further research.

Concerning learning processes, a three-step method has been conducted. In each of these steps, produced text (verbal and written) has been analysed differently (grammatically, contextually and semantically). Detected imprecise and abrupt expressions could mirror shortcomings within the configuration of the learning environment (and especially inside the investigated unit). But, again, some evidence has been presented which target a lack of self-determination in six of eight students' groups. It has to be kept in mind, that the learning has been studied in only one unit and that collective learning by means of interactions or further actions has not been considered. Exclusively learning processes related to the conceptual contents of the unit have been examined.

In summary, the results obtained are plausible and coherent to other science educational research. The integration of innovative teaching methods into concrete school and curriculum conditions is considered under professional development, especially the fact that teachers have to become more aware of their practice (e.g., Taitelbaum et al. 2008; Dass & Yager 2009). Besides, students' learning processes in autonomous settings accentuate the self-regulation component of learning (e.g., Pintrich 1999). With respect to the conceptualization within the analyzed unit, students could have needed more scaffolding in order to verbalize and their own experiences. In fact, these issues are included in other units of the learning environment (that recorded students couldn't experience during the planed implementation). Moreover, the role of teacher in final debriefing phases is essential.

Finally, it should be highlighted that the methodological integration of those environments has to be actively done by teachers themselves. Concerning the use of innovative instructional settings, researchers and teachers (and even principals) must work together during the design of research. Additionally, a previous analysis of autonomous learning skills of students must not be overlooked. A proper level of self-determination of the targeted populations (school, teachers and students) is hereby remarked as the key for a successful implementation of a

CBLE over the three investigated levels (external conditions, motivation and learning processes).

ANALYSIS OF SCIENCE TEXTBOOKS FOR A-LEVELS IN THE UK: ISSUES OF GENDER REPRESENTATION

Sabiha Sunar[1]
[1]Middle East Technical University, Ankara, TURKEY

Abstract: Curriculum materials play a role in making a discipline relevant and attractive to students and encouraging their involvement. This study has the objective of determining the gender balance in selected chemistry, physics and biology textbooks for A-levels in the UK. An exploratory study is conducted by analysing both the illustrations and the text for six textbooks adopting context-based approaches. Drawings and photographs were categorized whether they depicted males, females or both. Names appearing in the text were classified according to gender. Results revealed that males are heavily over-represented in the illustrations and 87% of the names appeared in the text belong to males. The message delivered through the more frequent depiction of males, even not intended, may be received by students as science is for all students in school but preserves males more.

Keywords: Textbook analysis, Gender representation, A-levels

INTRODUCTION

For the last two decades, science education has received an exceptional attention from stakeholders as a field of significant potential impact on a nation's success. Many efforts have been made to improve science teaching and learning in non-customary ways. Science education reform initiatives in the USA have targeted scientific literacy through inquiry experiences and skills "for all" (American Association for the Advancement of Science [AAAS], 1990, 1993; National Research Council [NRC], 1996). Many other countries directly or indirectly have shared the notion of educating all of their citizens and teaching science as inquiry as a major part of their educational reforms (Abd-El-Khalick et al., 2004).

Regarding this inclusive perspective; one may expect that both females and males are fairly portrayed in science textbooks that provide an important resource for teachers in schools. As various researchers indicate, textbooks are still being widely used in classrooms and continue to be an essential part of the curriculum. Science textbooks have played a dominant role in the teaching of science and have been mostly the science curriculum (Chiappetta & Fillman, 2007; Pizzini, Shepardson, & Abell, 1992; Kahveci, 2010). Furthermore, science textbooks are used as the primary organizer of subject matter at all levels of schooling (Chiappetta & Fillman, 2007).

Textbooks used in the teaching of many disciplines have been analysed to determine whether they provide fair and accurate coverage of particular topics or social groups. Evaluations of science textbooks involve various analyses from certain themes like gender equity (Elgar, 2004), questioning level (Pizzini et al.,1992), science vocabulary load (Groves, 1995), content accuracy (Hubisz, 2003), the inclusion of the nature of science aspects in biology (Chiappetta & Fillman, 2007; Irez, 2009) and chemistry (Abd-El-Khalick, Waters, & Le, 2008; Niaz, 2005) textbooks and misconceptions (King, 2010).

According to Elgar (2004), the amount of research effort devoted to the analysis of textbooks is in itself some indication of the importance many researchers attach to the messages that textbooks convey. Her study focuses on analysing a series of three lower secondary science textbooks used in Bruneian schools in terms of how equally females and males were represented in both illustrations and text. The results revealed that there is "clear gender imbalance in text and illustrations are in favour of males" (p. 891). In another study serving for a similar purpose, Walford (1980) examined the illustrations in 13 introductory science textbooks published in the 1970s, and found twice as many images of men as of women. He claims that gender bias in science textbooks may play a role in encouraging the view that "science is a boys' subject more than a girls' subject", and emphasizes the need to change 'the clear masculine face that science presents' (p.52). On the other hand, Potter and Rosser (1992) studied American life science textbooks for factors that might deter girls' interest in science. The researchers found a significant bias in favour of males in textbook illustrations similar to aforementioned studies. This, the authors believe, may convey the message that 'males are the norm in science' (p.669).

When the point comes to Turkish context, there are various studies focusing on gender issues in textbooks. As an outstanding example, Helvacioglu (1996) examined elementary level science textbooks published in Turkey between the years 1928 and 1995. Analysis of data led her to conclude that women were primarily depicted in traditional roles. In another study conducted by Özdoğru, Aksoy, Erdoğan, and Gök (2004), similar results were obtained. The researchers indicated that women were mostly assigned to roles like loving, caring, child-raising, at best as working in less prestigious jobs than males, if not housewives.

Keeping all these in mind, this study aims to investigate how males and females are represented in the textbooks adopting context-based approaches. The materials used in context-based courses vary from photocopiable worksheets to CD-ROMs but student textbooks comprise the backbone of each unit. Contexts and applications of science are used as a starting point for the development of scientific understanding throughout the textbooks. The shared aims of the courses in which these textbooks are used as the main resources are stimulating students' interest and enthusiasm for science and helping students acquire a better understanding of their natural environment without discriminating future science specialists and those who will not choose to continue with their study of science (Bennett & Holman, 2005). The most important reason of including textbooks used in context-based courses is that these courses hold the notion of "science for all". One may expect to see all aspects of equity throughout the textbooks. Considering all of these, this study aims to determine the gender balance of science textbooks used in A-levels (ages 16-18) in the UK.

METHODOLOGY

The six textbooks included in the study are selected due to adopting context-based approaches. The list of the books is presented at the end of the References.

In order to determine how equally females and males are represented in these textbooks, an unobtrusive research method, content analysis was applied. Based on counting and coding, illustrations and texts were analysed in detail. With regard to the illustrations, and following the methodology mentioned in the studies of Potter and Rosser (1992) and Elgar (2004), photographs and drawings were counted separately, as the impact on the reader of these two forms of illustration may be different. As in Walford (1980) and Elgar (2004), each photograph or drawing was classified according to whether it depicted only males or only females or both males and females. Fortunately, all the drawings were apparent enough to make a decision on the sex of the people portrayed. In just one instance, a drawing could not be categorized due to the lack of any gender reference on it. Photographs posed somewhat greater problems of analysis. In some photographs, it was impossible to determine the sex of people portrayed due to their positioning as very small, indistinct figures or wearing protective sports clothes and equipment like helmets that could belong to both males and females. Such photographs were not included in the analysis. There were also few photographs containing both distinct foreground figures and small, indistinct background figures which were categorized according to the sex of the foreground figures.

With regard to the analysis of the text, one of the aspects that seemed of interest from the point of view of gender representation was the number of people mentioned by name, and whether these were male or female. In this category different individuals were counted, rather than the total number of instances of names appearing in the text. Elgar (2004) suggested that counting each instance of a name would present a distorted picture, as the few individuals named mostly appear as protagonists in biographical narratives in which their names are mentioned repeatedly. In order to ensure this statement, each instance of a name was counted for two randomly selected textbooks which correspond to one third of the total number of the books analysed. It was seen that the discrepancy between the number of names that belong to males and females became greater due to having counted a male scientist's name 21 times and one other's 16 times. Furthermore, the names of scientists were only counted when they were mentioned as individuals. For instance, "Ziegler-Natta catalysis" was not counted until the text mentioned "Ziegler, the German scientist.." or "Haber process" is not counted until Fritz Haber was mentioned as a chemist.

RESULTS

Firstly, the frequency of males and females appearing in the illustrations in the textbooks were determined. From Table 1, it can be seen that photographs depicting males are more than three times as numerous as photographs depicting females. Moreover, the table shows that there are almost four drawings featuring males for every drawing featuring females. Thus, males are heavily over-represented in the illustrations.

The point where the textbooks differ is the way of the nouns used in the text. The analysis of the text revealed that it is common to mention individuals by their name. Totally, three of the four names (87%) mentioned in the text belong to males.

Textbooks	**Photos**			**Drawings**			**Nouns**	
	M	**F**	**B**	**M**	**F**	**B**	**M**	**F**
A	25	2	3	-	-	-	37	2
B	31	8	5	8	4	4	54	6
C	20	8	2	13	2	2	82	16
D	23	6	2	5	2	1	98	6
E	15	7	2	2	1	1	22	8
F	14	7	4	6	-	2	56	13
Total	**128**	**38**	**18**	**34**	**9**	**10**	**349**	**51**
%Total	**69.5**	**20**	**9.5**	**64**	**17**	**19**	**87**	**13**

Table 1. Frequency of different characteristics of representations of males and females

It is also considerable to mention that the only two photos depicting females in textbook A illustrates relatively passive roles like floating on the sea and representing suntanned skin. One of the two female names mentioned in the same textbook belongs to a fashion designer.

Although books B, E and F have more male images and names than females, an effort appears to have been made to avoid stereotyping with including photographs of females in scientific activities as chemist, astronaut, astronomer and researcher in a laboratory. Differing from other textbooks, B mentioned five of the female scientists with a Nobel Prize. The authors and publishers of book E have also apparently attempted to bear gender balance in mind when selecting names and illustrations but overall the numbers are in favour of males.

CONCLUSIONS AND IMPLICATIONS

This study is limited in the way that how any given text or illustration is interpreted depends in part on each individual's response to them. The power of the textbook, or even of the entire school curriculum, in the process of gender differentiation in science interests should not be overrated (Elgar, 2004). The gender variable interacts with other social variables such as race, religion, culture, and socio-economic status. Researchers dealing with gender-related issues should go beyond the textbooks.

However, the message delivered through the more frequent depiction of males, even not intended, may be received by students as science is for all students in school but preserves males more.

As Powell and Garcia (1985) mention, small representation of females in science-related occupational roles will limit the opportunities for young people to perceive females in scientific careers. They point out that illustrations in textbooks may be important in providing students with role models, enabling students to develop perceptions of themselves in possible societal roles in science, giving children the opportunity to view themselves as active participants in science-related activities, and providing children with positive self-concepts of themselves in relation to science (p.530). Their viewpoint is worthy of commendation and both the publishers and authors of textbooks should attempt to ensure further movement towards a balanced representation of the genders as new books are produced or revisions are made of existing books. However, it is not easy to achieve especially when the history of science aspect is included in the textbooks, a gender imbalance is inevitable. Such information can be accompanied by a discussion of the culture of the time, both societal and scientific. On the other hand, instead of emphasizing traditional roles of women, including females in scientific activities as chemist, astronaut, astronomer and researcher in a laboratory may be helpful. Furthermore, while selecting names that appear in questions, the authors and publishers should bear gender balance in mind.

In conclusion, textbooks are one of the major influences on students and more effort should be made to adequately address gender equity throughout the textbooks.

PRE-SERVICE SCIENCE TEACHER EDUCATION

ASSESSING PRE-SERVICE SCIENCE TEACHERS' TOPIC SPECIFIC PEDAGOGICAL CONTENT KNOWLEDGE (PCK): PRE-SERVICE SCIENCE TEACHERS' PCK OF ELECTROCHEMISTRY

Mehmet Aydeniz[1] *and Zubeyde Demet Kirbulut*[2]
[1]Department of Theory and Practice in Teacher Education, Graduate School of Education, The University of Tennessee, U.S.A.
[2]Department of Secondary School Science and Mathematics Education, Faculty of Education, Middle East Technical University, Turkey

Abstract: Electrochemistry has been cited as one of the most difficult chemistry concepts for high school and college students to comprehend. Previous research reports show that students at all levels of education hold misconceptions about electrochemistry. Science education literature reveals that science teachers' pedagogical content knowledge (PCK) plays a critical role in helping students to overcome these misconceptions. However, currently there is not an assessment instrument that can be used to measure and enhance pre-service science teachers' topic-specific PCK. The purpose of this study was to develop and test the validity of a PCK assessment tool for measuring pre-service science teachers' PCK of electrochemistry. After the instrument was conceptualized and developed, it was administered to 31 pre-service science teachers. The findings suggest that pre-service teachers have limited PCK in electrochemistry. The findings suggest that pre-service science teachers primarily focus on using hands-on learning strategies rather than strategies that will cognitively challenge their students to learn science. Moreover, the findings show that the designed PCK instrument has significant potential to provide valid and reliable information on the sophistication level of pre-service science teachers' topic specific PCK. In addition, the findings suggest that the aforementioned instrument can be used as a teaching tool to enhance pre-service science teachers' topic specific PCK.

INTRODUCTION

Teaching science for conceptual understanding is one of the pillars of science education reform (American Association for the Advancement of Science [AAAS], 1993). Teaching science for conceptual understanding requires teachers adopting a curriculum that accurately represents scientific ideas, one that is relevant to students' personal lives, and promotes students' learning of science through inquiry. This also mandates the presence of teachers who are knowledgeable of the subject matters that they teach and hold pedagogical understandings, knowledge and skills that will allow them to teach science for conceptual understanding (Gallagher, 2007). However, many science classrooms across the globe are filled with teachers who are not well prepared to teach science for conceptual understanding. While some of them cannot teach science for conceptual understanding because of their limited subject matter knowledge, others lack pedagogical sophistication needed to teach science for conceptual understanding. However, past research reveals that neither sophisticated knowledge of subject matter nor sophisticated knowledge of pedagogy alone can result in teachers teaching for conceptual understanding (Shulman, 1986). The argument holds that for science teachers to teach science for conceptual understanding, they need to hold sophisticated pedagogical content knowledge (PCK) (Park & Oliver, 2008).

PCK has been conceptualized in multiple ways. While some have defined PCK as the knowledge used to transform subject matter content into forms that are comprehensible to the students (Grossman, 1990; Shulman, 1986, 1987), others have provided more specific accounts of PCK and have defined PCK as the amalgam of science teachers' knowledge of context, curriculum, pedagogy and assessment that hold potential to result in conceptual understanding among the students when enacted in the classroom (Park, Jang, Chen, & Jung, 2011).

Shulman (1987) defined PCK as "the blending of content and pedagogy into an understanding of how particular topics, problems, or issues are organized, represented, and adapted to the diverse interests and abilities of learners, and presented for instruction" (p.8). Carter (1990) understood PCK as what teachers recognize about their subject matter and how they convert that knowledge into curricular events within the classroom. Grossman (1990) defines four essential components of a teacher's PCK: a) teachers' beliefs and knowledge of teaching a particular topic, b) knowledge of curriculum and curriculum materials, c) knowledge of common misconceptions held by students related to a particular domain of knowledge, and d) knowledge of particular instructional strategies and representations related to a particular topic. Park and Oliver (2008) built on this definition and added a new component called, "knowledge of assessment of students learning". Although PCK has been defined in slightly different ways, the transformation of content knowledge by the teachers for the purpose of effective teaching and enhanced student learning lie at the center of PCK (Park & Oliver, 2008).

Baxter and Lederman (1999) state PCK is constituted not only by what a teacher knows but also by "what a teacher does", and the reasons for the types of actions that he/she takes in relation to teaching a specific topic (p. 158). Shulman (1987) further argues that PCK involves teachers "from being able to comprehend subject matter for themselves, to becoming able to expose subject matter in new ways, reorganize and partition it, clothe it in activities and emotions, in metaphors and exercises, and in examples and demonstrations, so that it can be understood by students" as well (p. 13). These definitions imply that PCK must be understood and explored at two levels: 1) espoused PCK and 2) enacted PCK.

Espoused PCK refers to the amalgam of science teachers' knowledge of subject matter and their understanding of pedagogical strategies necessary to make a specific science topic comprehensible to their students. Espoused PCK is like a concept map that guides science teachers to make instructional decisions, the use of particular reinforcement materials and instructional strategies, while providing assessment of student learning (Park & Oliver, 2008). Teachers must have knowledge of what students know about a topic and areas of likely difficulty to employ PCK effectively (Park & Oliver, 2008). This means that pre-service teachers have to understand the knowledge of students' conceptions of particular topics, their learning difficulties, motivation, and diversity in their abilities, learning styles, interests, developmental level and language proficiency (Park & Oliver, 2008). Having such knowledge does not necessarily mean that they will use that knowledge in their teaching of science. When such knowledge get enacted in the classroom we call it enacted PCK. Enacted PCK refers to the type of PCK that can be observed during teaching. Park and Oliver (2008) maintain that enactment of PCK is a metacognitive activity. This implies that while the espoused PCK can help science teachers to design a lesson that reflects the best practices, enacted PCK is responsive to the students' learning needs as they present themselves during teaching.

The purpose of this study was to develop and test a PCK assessment tool to measure pre-service science teachers' PCK of electrochemistry. The focus of this study is espoused PCK. The researchers chose to focus on espoused PCK because measuring pre-service science teachers' enacted PCK is very labor-intensive and many science teacher educators lack human and financial resources to assess pre-service science teachers' topic specific PCK. For instance, it is not practical for a science teacher educator to spend two weeks on observing each of the 30 pre-service science teachers enrolled in their classrooms. The researchers focused on pre-service science teachers because pre-service science teachers often have a hard time converting their content knowledge into PCK, due to their limited experiences with teaching science for a diverse group of students. Also, electrochemistry is one of the most difficult subjects to learn for both teachers and students (Johnstone, 1980). Many researchers have documented that students have considerable difficulty in terms of understanding of electrochemical concepts (Garnett & Treagust, 1992; Sanger & Greenbowe, 2000). Given the abundance of students' misconceptions related to the electrochemical concepts, developing an instrument that we can use to measure pre-service science teachers' PCK of electrochemistry proves to be important. Our aim was to make several key elements of reform-based science curriculum, instruction and assessment visible to the pre-service science teachers by engaging them in reflection through a PCK assessment tool STSPCK (Secondary Teachers' Scientific Pedagogical content Knowledge) designed by the authors.

METHODS

Context

This study took place at a respected teacher education program in Turkey. The university where this study took place hosts 25000 students in 26 different majors. There are nine departments in the college of education at this university. All education programs are based on the five-year Holmes model. All pre-service teachers are required to complete a B.Sc. degree before they start to take education courses. Then, students spend one and a half year taking education courses in order to complete the teacher education program. All students graduate with a master's degree in their field of study and a license to teach in the secondary schools.

Participants

The participants consist of 31 pre-service chemistry teachers; 15 males and 16 females. Of the 31 participants, 10 were pre-service chemistry teachers in their senior year and 21 in their junior year of college. All pre-service chemistry teachers had completed the required subject matter courses prior to admission to the masters program and are currently taking pedagogical courses.

Data source and data collection procedure

Data source includes pre-service science teachers' responses to the STSPCK (Secondary Teachers' Scientific Pedagogical content Knowledge) instrument. After we granted the permission from human subjects committee, the students were informed of the purpose of the study and their participation in the study was sought. All 31 students agreed to participate in the study. After the students agreed to participate in the study, we administered the STSPCK to the participants.

STSPCK was developed by the researchers to assess pre-service chemistry teachers' PCK of electrochemistry. It consists of three parts with 30 items. The first part measures pre-service chemistry teachers' knowledge of reform-based curriculum and includes seven items. The second part consists of nine items assessing pre-service chemistry teachers' knowledge of reform-based instructional strategies. The third part includes 14 items regarding reform-based assessment and evaluation strategies. The pre-service chemistry teachers were asked to provide explanations and examples for each item considering electrochemistry, specifically "the galvanic cells".

The participants completed the STSPCK in one and a half hour. One week after the participants completed the STSPCK we asked the participants to use the STSPCK instrument and discuss their answers to the STSPCK in groups of two to four. The participants discussed their answers to the STSPCK instrument for one hour. These conversations were audio taped for analysis.

Data analysis

Data analysis was conducted in two stages. First, two authors read students' responses to the STSPCK instrument to identify statements that reflected the attributes of a sophisticated PCK and those that lacked such sophistication. These elements include: a focus on student-centered approaches to teaching science, promoting students' acquisition of scientific epistemologies, and assessing students' learning in science. In our analysis, we were interested in the specificity and quality of examples and strategies provided by the participants. By quality we mean examples or strategies that held the highest potential for promoting students' conceptual understanding of electrochemistry.

The STSPCK has three categories: curriculum, instruction, and assessment. We first analyzed participants' responses in each category and graded the quality of their responses for each category based on a scale that ranged from 1-10 with 1 representing the lower level of PCK knowledge and 10 highest level of PCK. Then, we gave each participant a cumulative score for each category: curriculum, instruction, and assessment. Finally, we categorized participants into 1) those that have naïve PCK, 2) those that have a developing PCK, and 3) those that have sophisticated PCK.

RESULTS

The findings indicate that the majority of the participants held naïve pedagogical content knowledge (PCK) related to electrochemistry as expected. We present the results under three categories: curriculum, instruction, and assessment.

Knowledge of curriculum

The findings indicate that the majority of participants held underdeveloped understandings of what it would take to make science curriculum reform-based. We analyzed participants' responses from two perspectives: student-centeredness of the instructional strategies expressed and the specificity of the instructional strategies that they expressed. We analyzed the strategies proposed by the participants in terms of their alignment with the science learning goals promoted by science education reform documents such as the NSES and Benchmarks for Scientific Literacy (AAAS). More specifically, we looked at the emphasis on inquiry, relevance of curriculum to everyday life, and equity. The participants were placed into one of the following categories in terms of the sophistication level of their PCK: naïve, developing, or sophisticated pedagogies.

In terms of the student-centeredness of the proposed strategies, 12 participants were placed in the naïve category, 12 were into the developing category, and six were into the sophisticated category. In terms of the specificity of the strategies that the participants expressed, 16 participants were put into the naïve category, 10 were into the developing category, and four were into the sophisticated category.

While the majority of participants emphasized the importance of inquiry-based learning, making science relevant to students' personal lives, making connections between the content of their teaching and students' cultural backgrounds, using problem-based curriculum, they failed to provide instructional examples that are specific to the teaching of galvanic cells. Similarly, findings indicate that the participants failed to discuss how the approaches that they adopted would help their students to achieve learning objectives. The results for this category are summarized in Figure 1.

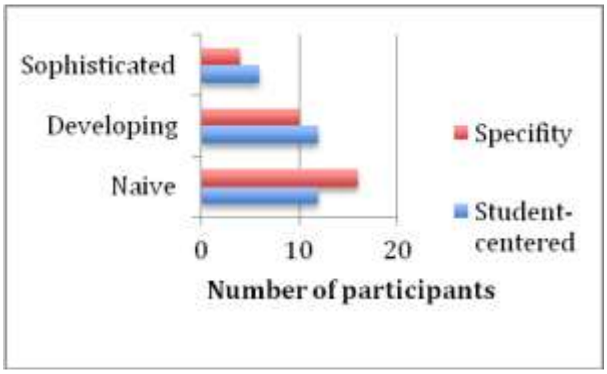

Figure 1. Participants' knowledge of curriculum

Knowledge of instruction

The results of our analysis show that the majority of the participants expressed underdeveloped understanding or knowledge of reform-based instructional strategies in the knowledge of instruction category. When the participants' responses were evaluated based on the criteria of student centeredness, 11 were placed under the naïve category, 11were under the developing category, and eight were under the sophisticated category. However, when the participants' responses were evaluated based on the specificity of the instructional strategies and examples, the number of participants under the naïve category went up from 11 to 16, of those in the developing category dropped to 10, and of those in the sophisticated category dropped from eight to four. These statistics are summarized in Figure 2.

While the participants were able to provide general instructional strategies such as using constructivist teaching methods, making the teaching of electrochemistry relevant to students' lives, engaging students in group-based activities, they failed to provide specific instructional strategies and examples that held potential to facilitate students' learning of science in ways that are consistent with those espoused in science education reform documents and current science education literature.

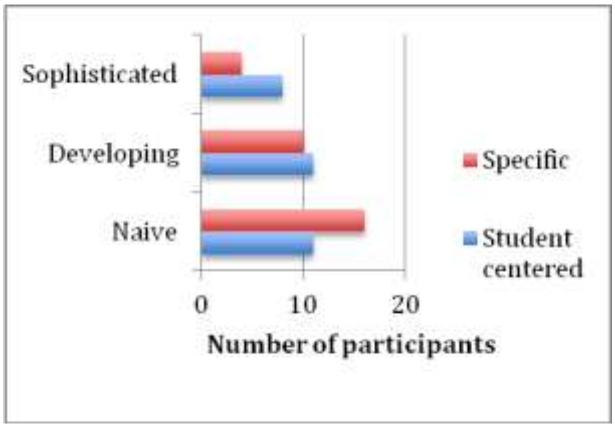

Figure 2. Knowledge of instruction

Knowledge of assessment strategies

The findings show that the participants had the most difficulty in the assessment category. When the participants' responses were evaluated based on the criteria of student centeredness, 15 were placed under the naïve category, six were under the developing category and nine were under the sophisticated category. However, when we used the criteria of the specificity, the number for participants who fell under the naïve category went from 15 to 19, of the developing category went from six to eight and of those that were placed in the sophisticated category dropped from nine to three. These statistics are summarized in Figure 3.

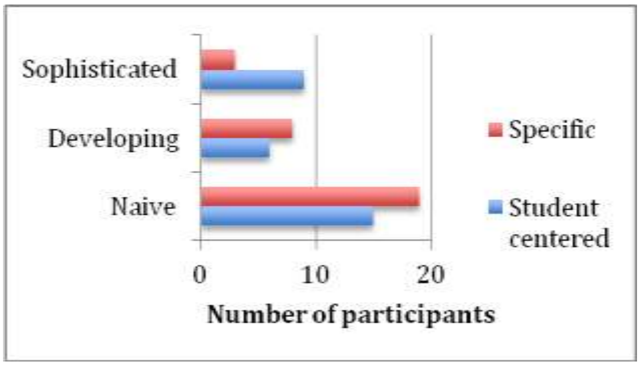

Figure 3. Knowledge of assessment

CONCLUSIONS AND IMPLICATIONS

There has been a growing interest in finding ways to enhance pre-service and in-service science teachers' PCK (Park & Oliver, 2008; Park et al., 2011). This emphasis on PCK is justified based on the assumption that a sophisticated PCK can make a significant impact on the quality of instruction that the students receive and thus the quality of learning the students experience in the classroom (Grossman, 1990; Park et al., 2011). For instance, Mansor, Halim and Osman (2011) looked at the impact of science teachers' PCK on students' conceptual understanding of cellular respiration and found that teacher PCK has a positive influence on students' conceptual understanding of cellular respiration. Traditionally, science educators have measured the sophistication level of teachers' PCK by having them to design a lesson plan or teach a mini lesson on a specific topic. These methods have limitations in that we cannot have pre-service science teachers to design a lesson for every topic and have no time to watch and evaluate students' mini lessons for every science topic in a semester-long, three-hour a week methods courses. Therefore, science educators continue to work on finding new ways to enhance pre-service science teachers' PCK of specific science topics. The results of this study show that the STSPCK can reliably measure pre-service science teachers' PCK. In addition, STSPCK can be used to help pre-service science teachers to identify their pedagogical needs so that science teacher educators could help pre-service science teachers to develop sophisticated PCK before they enter the classrooms of public and private K-12 schools. The current efforts of the researchers focus on using the STSPCK in physics concepts (i.e. momentum) and biology concepts (i.e. molecular genetics).

[3]Institute of Physics of São Carlos, University of São Paulo

Abstract: This work aims to investigate in the light of cognitive maps the beliefs of future teachers of Physics when working in a context of a curriculum innovation, particularly, the inclusion of Modern and Contemporary Physics topics into the High School curriculum. Our research methodology is of qualitative nature, of the case study type, and the data collection instrument consisted of a Likert questionnaire with 28 items carried out at the beginning and in the end of a mini-course on Particle Physics of 40h with a group of 11 preservice teachers on the Physics Teacher Training Course of the São Carlos Institute of Physics, at the University of São Paulo/Brazil, in 2009. As analytical framework for analyzing the collected data to build cognitive maps at the beginning and end of the mini-course. Among the findings to highlight to the epistemological beliefs: phenomenology, mathematical formalism, conceptual framework and ontology. For the didactic-pedagogical beliefs highlight: hierarchy of prerequisites, methodology of teachers, content selection, proposed activities and evaluation. Thus, among the principal implications of this work we would highlight: the need to provide teachers in their initial training with means to help them recognize their beliefs regarding Modern and Contemporary Physics, and instruments for evaluation and possible intervention with regard to their beliefs about the teaching and learning of Modern and Contemporary Physics topics in High School.

Keywords: Cognitive Maps, Curriculum Innovation, Beliefs, Qualitative Research, Modern and Contemporary Physics Teaching

BACKGROUND, FRAMEWORK AND PURPOSE

In recent decades, a curriculum innovation movement has been observed in several countries whose focus shifts from the content needs to the learner needs, what makes learners more motivated in learning situations potentially important and useful to them.

Some works highlight the involvement of teachers as a key-point for the success of a curricular innovation (Brown & McIntyre, 1978). They also call attention to the risks of non-adhesion and/or a failure to understand the proposed innovation on the part of the teachers (Fullan & Hargreaves, 1992). The possibilities of success increase significantly when the demand for change comes from within the teaching system itself, and is not seen by the teachers as an imposition of curriculum reformers.

On the other hand, despite these proposals for curriculum innovation developed in many countries, the traditional teaching has remained resistant to the new changes, and this is due largely to the knowledge and beliefs that teachers hold about the nature of their discipline, their personal and professional identity, as well as teaching and learning of specific contents (Davis, 2003; Feldman, 2002; Tobin & McRobbie, 1996; Pintó, 2002).

In this work our goal is to investigate in the light of cognitive maps the beliefs of future teachers of Physics when working in a context of a curriculum innovation, particularly, the inclusion of Modern and Contemporary Physics topics into the High School curriculum.

METHODOLOGY

Our research methodology was of qualitative nature, case study type, and the data collection instrument consisted of a Likert questionnaire with 28 items carried out at the beginning and in the end of the mini-course of 40h with a group of 11 preservice teachers on the Physics Teacher Training Course of the São Carlos Institute of Physics, at the University of São Paul o/Brazil, in 2009.

The preservice teachers participated in a mini-course on the subject of “Particle Physics”, totaling 16 hours, with the objective of providing conceptual tools to prepare them to work with the proposed topics. During the mini-course, teaching activities were developed and applied which dealt with topics such as: Rutherford scattering, particle detection, laws of conservation, fundamental interactions, the standard model of elementary particles and the connection between Cosmology and Particle Physics.

For this work, it was selected one preservice teacher’s data. The choice of this future teacher as an example to illustrate our analysis is justified due to the fact that his answers to the questionnaire are more representative of changes over the mini-course than the responses provided by other participants. This prospective teacher will be identified as Jonah. Below, it was made explicit his synthetic profile:

Teacher	Profile
Jonah	He always wanted to be a teacher and he considers the profession as very important, since the physics is in everything around us. The fact that he had always liked mathematics, mechanical and electrical objects helped him to choose to be a physics teacher. He would wish to pursue the profession after completing undergraduation.

After participating in the mini-course, in a second stage of approximately 20 hours, the preservice teachers had the task of analyzing the content studied in such a way as to adapt it and organize it into a teaching module, lasting 4 hours, which was delivered to High School students.

In recent years, cognitive maps have been used as analytical tool to interpret the Likert questionnaires in Science Education (Mellado et. al., 2002; Da-Silva, C., Mellado, V., Ruiz, C., & Porlán, R, 2007). In this research, they were used in order to structuring more comprehensive scenery of preservice teachers’ beliefs on different dimensions.

RESULTS

We built the initial and final cognitive maps highlighting the changes that occurred in the responses of preservice teachers from the beginning to the end of the mini-course. For such a differentiation, geometric figures and color changes were used between the five possible responses: strongly agree (dark green circles), agree (green circles), strongly disagree (dark red squares), disagree (red squares) or indifferent (yellow hexagon). About the colors and the questions that are listed in some geometric figures in the next two pages, it is important to clarify that all squares with red and dark red should be read negatively, because they report the disagreement with the item. The circles with green and dark green should be read in a positive way because they report the agreement with the item.

Therefore, we seek to determine the changes in Jonah’s conceptions both about the nature of knowledge of Modern and Contemporary Physics and his teaching and learning from the beginning to the end of mini-course.

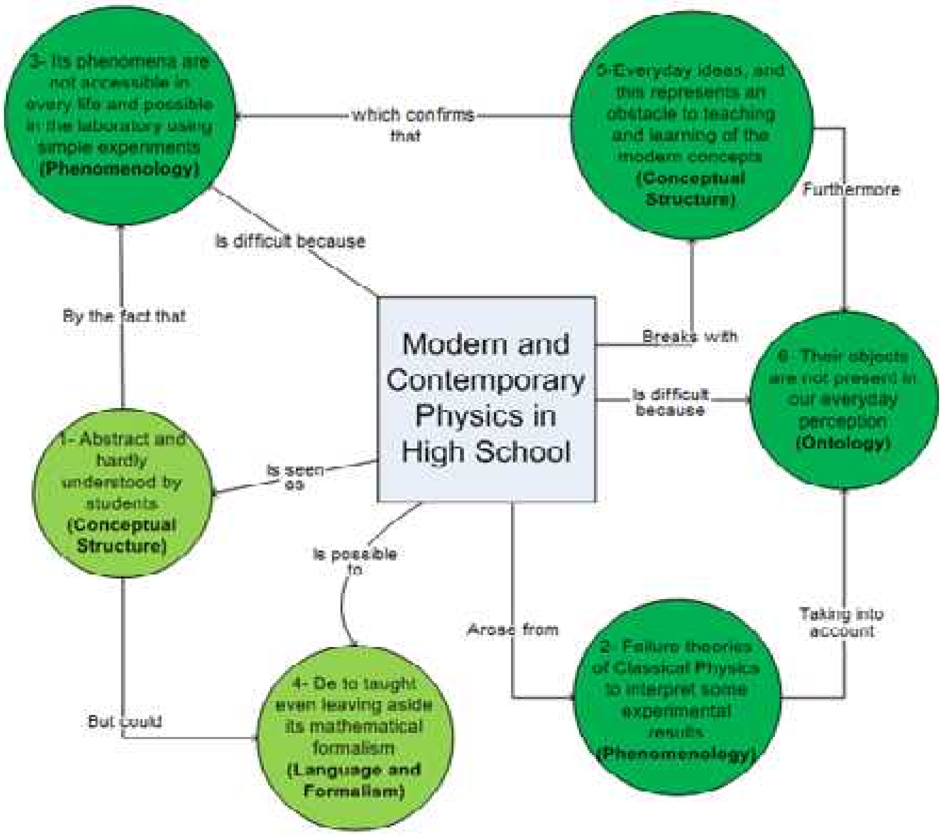

Fig. 01: Initial Epistemological Beliefs

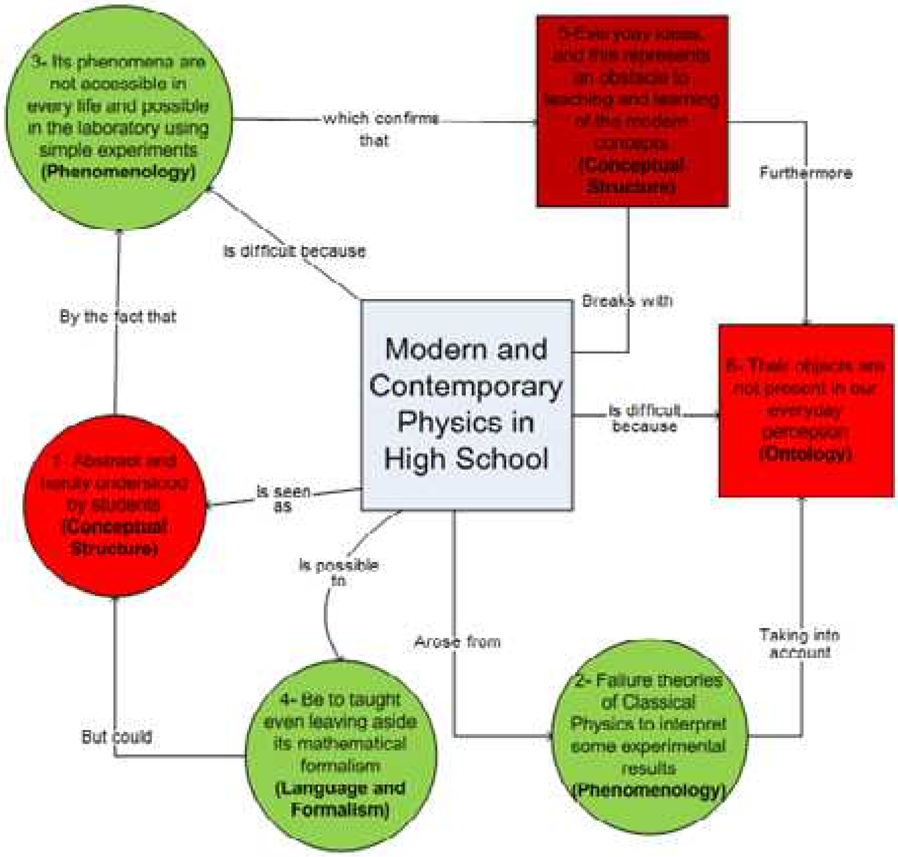

Fig. 02: Final Epistemological Belief

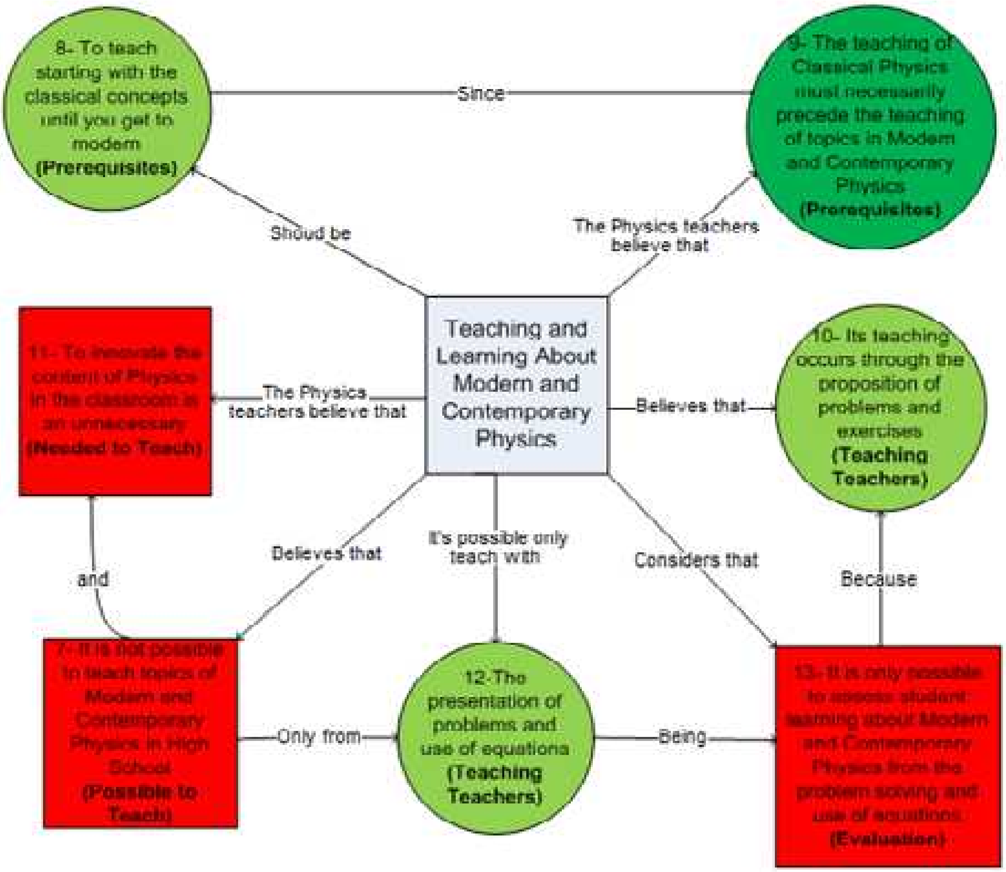

Fig. 03: Initial Didactic-Pedagogical Beliefs

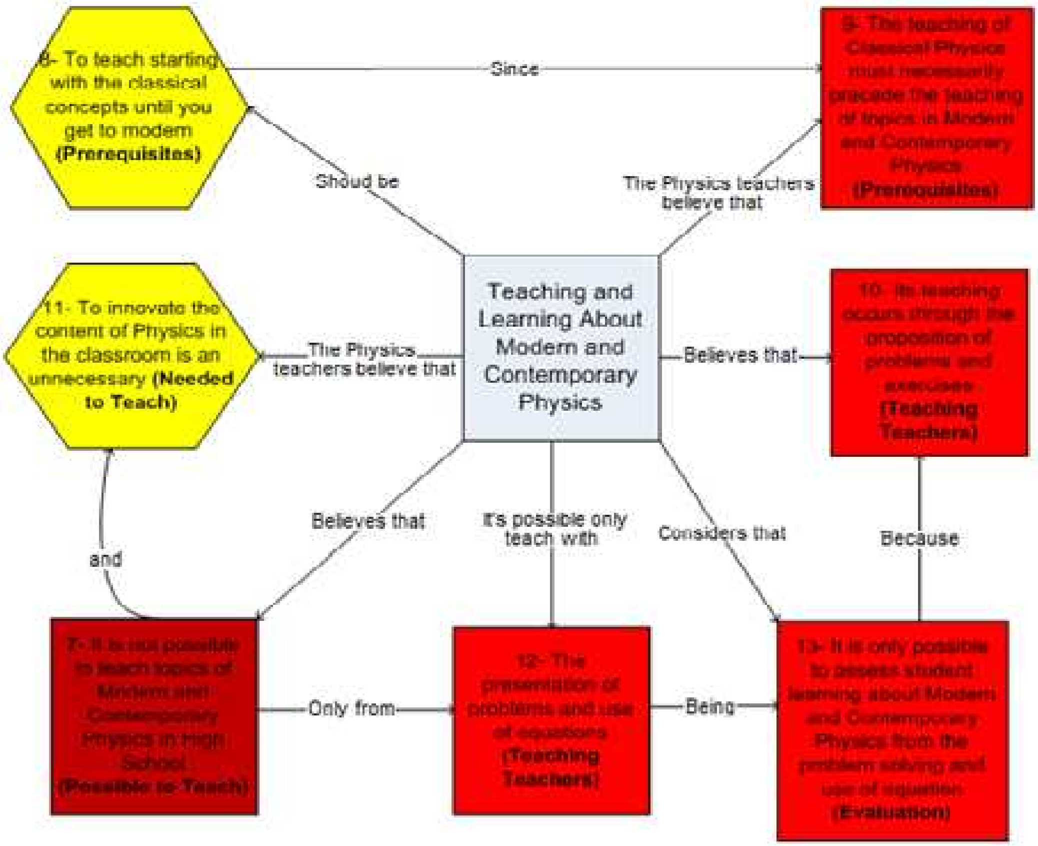

Fig. 04: Final Didactic-Pedagogical Beliefs

With respect to Jonah's epistemological beliefs (Fig. 01 and 02), we note that the question 4 was the only case in which changes were not observed, all others had some kind of change on a larger or smaller scale. Regarding to question 1, he has changed from agree to disagree, at some point Jonah noted that the Modern and Contemporary Physics was not always seen as abstract and difficult to understand; in questions 2 and 3 the changes were not as perceptible, in the beginning he was fully in agreement and in the end he only agreed; in question 5 there has been a big change, because in the beginning he agreed and in the end he fully disagreed that modern concepts break with everyday ideas, so it was not an obstacle to teaching and learning process; in question 6 there was also a significant change, in the beginning of the mini-course he fully agreed with the question and in the end he disagreed.

With respect to Jonah's didactic-pedagogical beliefs (Fig. 03 and 04), we note that in question 7 he disagreed in the beginning and in the end he disagreed completely; with respect questions 8 and 11, both were answered as indifferent in the end of the mini-course, the difference is that in question 8 he initially agreed and in the question 11 he disagreed; in the response to question 9 there has been a clearer change, because at the beginning of the mini-course he agreed fully with the question and in the end he disagreed; questions 10 and 12 had the same kind of change, at the beginning Jonah agreed and in the end disagreed.

In the light of the results obtained from Jonah's beliefs and from what the literature highlights, we would emphasize that it is necessary to know even more about the beliefs of future teachers regarding topics of Modern and Contemporary Physics and the their teaching at the High School level and that this will be an important first step in the attempt to set into action strategies to pursue changes and evolutions in the educational beliefs of preservice teachers with regard to the proposals of curricular innovation.

CONCLUSIONS AND IMPLICATIONS

We stress the importance of considering, for professional development, subjective variables present in preservice teachers, such as behaviors, attitudes, beliefs and individual life histories. In our investigation the future teachers were caught up in a bureaucratic discourse, which was more focused on completing an academic ritual, for example, concluding the activities on time, than being actively involved in the teaching activities proposed. Another belief identified in the statements of preservice teachers is the fact that they never acquired in their own school days any experiential knowledge related to topics of Modern and Contemporary Physics, compared with themes related to teaching Classical Physics.

The training courses for teachers will have to be even more geared to taking into consideration this research data in order to better prepare the teachers in this sense. Thus, among the principal implications of this work we would highlight, among other aspects: the need to provide teachers in their initial training with means to help them recognize their beliefs regarding Modern and Contemporary Physics, and instruments for evaluation and possible intervention with regard to their beliefs about the teaching and learning of topics of Modern and Contemporary Physics in High School curriculum.

An interesting perspective for research and teaching strategy for preservice physics teachers would discuss with them about their own beliefs concerning to the implementation of Modern and Contemporary Physics in high school. For this, cognitive maps can provide a good view of the restructuring of future teacher’s responses. Furthermore, when teachers educators seek to evaluating and discussing the future physics teachers’ beliefs on the insertion of Modern and Contemporary Physics in high school, they will benefit their students and start to develop strategies to cope with these beliefs along their initial or in service training courses.

ANALYSIS OF A TEACHING EXPERIENCE IN THE CONTEXT OF A CURRICULUM INNOVATION

Marcelo Alves Barros[1], Edson Cesar Marques Filho[2], Carlos Eduardo Laburú[3]
[1]Institute of Physics of São Carlos, University of São Paulo
[2]Institute of Physics of São Carlos, University of São Paulo
[3]Physics Departament, State University of Londrina

Abstract: Currently there is a movement to reform the curriculum in many countries and the teachers beliefs in respect of how they teach what they know, about the contents itself and how these factors can change over time are aspects that need to be better understood during a curricular innovation in the classroom (Davis, 2003). In this work our goal is to advance the identification and analysis of the beliefs of preservice Physics teachers on the inclusion of Modern and Contemporary Physics topics in High School curriculum. We used the findings summarized by Pajares (1992) about educational beliefs in order to understand and establish some basic guiding principles to this research. Our methodology was qualitative nature in which was used semi-structured interviews as a tool for data collection. We applied a Content Analysis (Bardin, 1986) as an analytical framework. The interviews were conducted with a group of 11 preservice teachers on the Physics Teacher Training Course of the São Carlos Institute of Physics, at the University of São Paulo/Brazil, in 2009. It was possible to deduce from the beliefs studied the importance of working themes of Modern and Contemporary Physics in teachers training courses in terms of contents and educational to provide teachers with means of plan and make decisions with greater confidence to implement themes of Modern and Contemporary Physics in high school. Implications of the insertion of Modern and Contemporary Physics in curriculum are discussed.

Keywords: Physics Education, Teacher Training, Curriculum Innovation, Modern and Contemporary Physics, High School Curriculum.

BACKGROUND, FRAMEWORK AND PURPOSE

Currently there is a movement to reform the curriculum in many countries emphasizing the shift from a teaching paradigm that focuses on the transmission of content to one that emphasizes the needs of students so as to make them active individuals, through activities that are potentially meaningful to them and that are perceived as useful and relevant to their lives.

The teaching based on transmission of content, however, has resisted to new curriculum guidelines in function, in large part, of the teachers knowledge and beliefs about the nature of their disciplines, their personal and professional identities about teaching and learning of certain specific contents (Pinto et al., 2001).

In other words, the way in which teachers learn to teach what they know, how they form their knowledge, how they change over time etc… are factors that need to be better understood during a curricular innovation in the classroom (Davis, 2003).

Likewise, Tobin and McRobbie (1996) point to the existence of four cultural myths that surround the beliefs of teachers concerning the science curriculum: the myth of the transmission, the myth of efficiency, the myth of the rigor, and the myth of students' preparation for exams.

In this context lies this study, whose aim is to advance the identification and analysis of the beliefs of preservice physics teachers on the inclusion of Modern and Contemporary Physics in high school.

RATIONALE

Pajares (1992) summarized many findings on the study of beliefs in order to establish some basic guiding principles to guide further research in this direction: individuals' beliefs strongly affect their behavior, they are formed early and tend to perpetuate themselves even in face of contradictions caused by reason, time, experience or education and earlier a belief is incorporated, the harder it is to change it.

Moreover, changes in beliefs during adulthood are relatively rare phenomena in which occur general and deep changes - 'gestalt shifts' - in someone. Individuals tend to cling to beliefs based on incomplete or incorrect knowledge even after scientifically correct explanations are presented to them.

Finally, beliefs about teaching are already well established when a student arrives at university and those beliefs contribute to the definition of tasks and selection of cognitive tools with which to interpret, plan and make decisions regarding such tasks.

METHODOLOGY

The methodology of this research was of qualitative nature, case study type, in which was used semi-structured interviews as tools for data collection. We applied a Content Analysis (Bardin, 1986) as an analysis tool with the particularity that the same record unit could be related to more than one subcategory.

The interviews were conducted with a group of 11 preservice teachers on the Physics Teacher Training Course of the São Carlos Institute of Physics, at the University of São Paulo/Brazil, in 2009. The prospective teachers participated in a mini-course related to topics of Modern and Contemporary Physics totaling 16 hours with the aim of providing conceptual tools to them and prepare them to work with the proposed topics.

For this work, it was selected one undergraduate’s results. This prospective teacher will be identified as Roberto. Next, it was made explicit his synthetic profile:

Teacher	Profile
Roberto	He chose the teacher program according the following factors: his empathy with the physics, the availability of the course at night, his need to work during the day, and the fact that he enjoys teaching. But he does not intend to practice immediately, since they already have a steady job as a civil servant now, but he would intend to be a teacher in the future.

Fig. 1: Profile of undergraduate investigated

After participating in the mini-course, at another stage of approximately 20 hours, the student teachers had the task of analyzing the content studied in order to adapt it and organize it into a teaching module of 4 hours for high school students.

RESULTS

We present some of Roberto’s record units, as well as their related subcategories which were built from an inductive process in Fig.2.

It was possible organize the subcategories into more embracing categories as well: epistemological and didactic-pedagogical. Thus, we present in Fig. 3 a general scheme that helped us to organize and analyse the record units, our initial raw data, in order to make possible in the sequence to infer the prospective teachers' beliefs.

"It's the Modern and Contemporary Physics you get there the last hundred years which is the part that we see applied in all places of high-tech industry, everywhere you see the physics of the last hundred years." ***Everyday Content; Applied Content***
"I think it has advantages you teach Classical Physics before the Modern because students end up working with more concrete things, than work with abstract contents of Modern and Contemporary Physics." ***Teaching with Prerequisites; Abstract Content***
"When a person does not understand Modern and Contemporary Physics, you have to have a strategy to achieve that goal, to circumvent the mathematical formalism and circumvent the difficulties of abstraction of the contents of Modern and Contemporary Physics (...)". ***Knowing how to use Teaching Strategies; Difficult to Teach; Teaching with Mathematical Formalism; Abstract Content***
"(...) I learned modern physics in a non-teaching for high school students. In principle, what you do is teach the way you learned. At this time you cannot because students will not have especially the mathematics tools to understand what I teach. " ***Knowing how to use Teaching Strategies; Difficult to Teach; Teaching with Mathematical Formalism***
"I think it is going to need training teachers. I had access to training, right? I was trained, but for teachers already in service is not easy you get our Curriculum which has Modern and Contemporary Physics and apply that. " ***Knowing how to use Teaching Strategies; Difficult to Teach; Possible to Teach***

Fig. 2: Some record units from the interview with Roberto

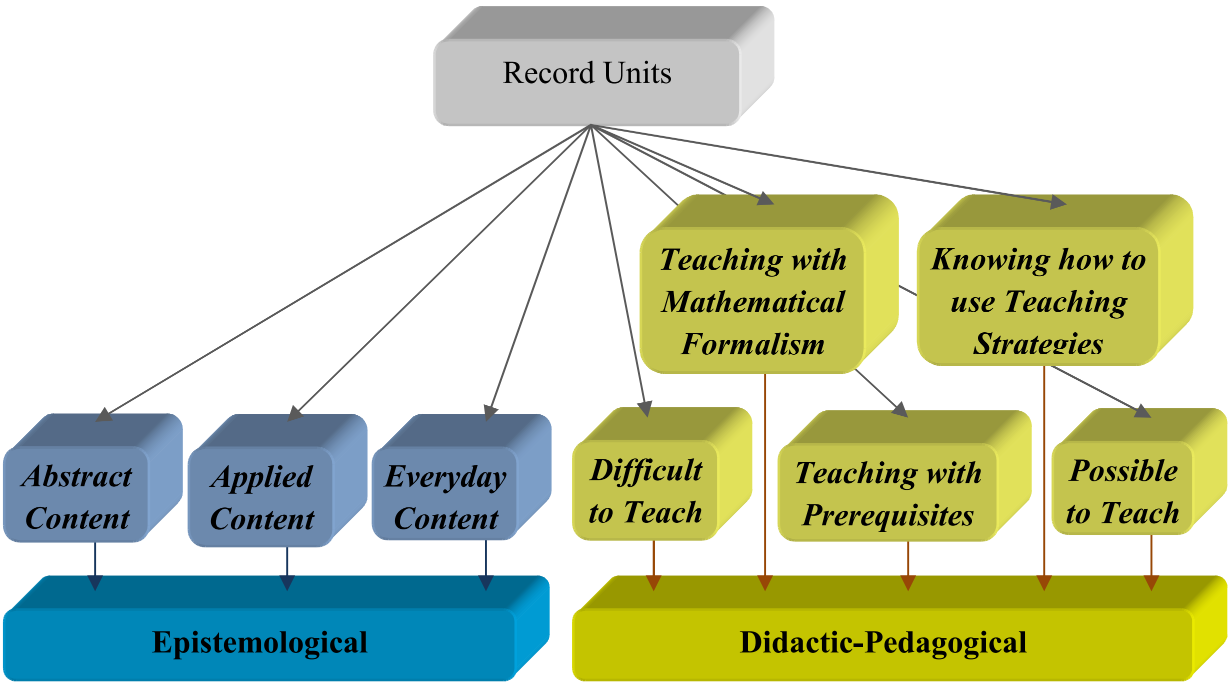

Fig. 3: General scheme of record units organization

From the interviews it was possible to infer the following epistemological and didactic-pedagogical beliefs of future teachers:

- The concepts of Modern and Contemporary Physics are abstract, while the classical concepts are more concrete;

- It is valid and possible to teach topics of Modern and Contemporary Physics in high school because they are content that may be applied in everyday life, but the feasibility of teaching is improved, especially when the teacher has a preparedness to deal with such topics in high school level;

- It is preferable but not necessary, that students know well classical concepts to work with Modern and Contemporary Physics concepts;

- Teach Modern and Contemporary Physics is something difficult due to no solid references of how to teach these topics to High School;

- The mathematical formalism withdrawal would be more difficult to teach Modern and Contemporary Physics in high school, because many contents of Modern and Contemporary Physics need mathematical rigor. But at the same time believes that students in high school would be unable to understand much of this formalism.

CONCLUSIONS AND IMPLICATIONS

Roberto's belief that classical physics is more concrete was created during his years of study along their initial formation. This belief was formed early and it tends to perpetuate itself even in face of contradictions and only through a great effort to explain how abstract classical physics concepts also can be is that such belief may be revised by future teachers and we can assume in this case that this phenomenon is general to the extent that this belief was built in common educational situations to many teachers.

Moreover, although this conclusion be obvious, it is possible to deduce from the beliefs of this teacher the importance of working themes of Modern and Contemporary Physics in teachers training courses in terms of contents and in terms of pedagogy to provide teachers with means of plan and make decisions with greater confidence to implement themes of Modern and Contemporary Physics in high school, especially when the teacher realizes that he himself has no references on how to teach these topics to high school.

Furthermore, as the beliefs about teaching are well formed when a preservice teacher arrives at university, only a good work in the initial teacher training courses can lay a solid foundation for consolidation of their beliefs about the inclusion of Modern and Contemporary Physics in high school, although this achievement is still a great challenge, since there is no consensus on how best to proceed in this sense.

We aim that stimulate in prospective teachers the belief that it is preferable but not required, that students know well the classical concepts for working with concepts of Modern and Contemporary Physics helps to create a more flexible environment for the insertion of Modern and Contemporary Physics in classroom.

We hope to contribute to the research focusing on teacher beliefs in a context of curriculum innovation, so that among the main implications of this work, we highlight the available compilation of the beliefs of teachers about the inclusion of topics in Modern and Contemporary Physics in High School.

This repertoire can be configured as a set of information for teacher trainers who wish to compare these results with those of their own students and seek to influence positively on their beliefs, improving the initial training of its undergraduates in what concerns the insertion of Modern and Contemporary Physics in High School.

Faculty of Education, University of Extremadura, 06071-Badajoz, Spain [mariabm@unex.es]

Abstract: A study is described of the self-efficacy of prospective primary teachers, and the relationship between this self-efficacy and the emotions they see themselves as having as future science teachers. The study was conducted through a questionnaire completed by 188 students in initial primary teacher education at the University of Extremadura during the academic year 2009-10. The results showed them to believe in their positive self-efficacy, and to have mostly positive emotions towards the Nature Sciences (biology and geology) but negative towards the Hard Sciences (physics and chemistry). Their self-efficacy had hardly any influence on their emotions in the Nature Sciences, but the students with positive self-efficacy had more positive emotions and fewer negative emotions in the Hard Sciences than those with negative self-efficacy.

Keywords: self-efficacy, emotions, science education, initial teacher education, primary teachers

BACKGROUND AND FRAMEWORK

For many years, the study of emotions and feelings had been relegated to the fields of literature and art. Years ago, it would have seemed frivolous to introduce the study of these terms into education (Segura & Arcas, 2007), and even more so to relate them with specific school content or with other concepts such as self-efficacy. Fortunately today however, the idea that teaching is an emotional practice that involves both cognitive and affective processes is often fully accepted by researchers and educators (Garritz, 2009; Hargreaves, 2000; Shapiro, 2010; Van Veen et al., 2005).

In relation to science education, however, the affective has been far less investigated than the cognitive, and has usually been related more specifically to attitudes rather than to emotions. The First and Third Handbooks on Science Education provided two extensive reviews of attitudes (which included the emotions) in science learning. These were in the chapters of Simpson et al. (1994) and Koballa & Glynn (2007), respectively. In the Second Handbook, Bell (1998) dealt specifically with the science teacher's affective dimension.

Bandura (1977) defines self-efficacy as the belief in one's own ability to organize and execute the actions that one's profession requires. The notable influence of teachers' beliefs in their self-efficacy on their pupils' performance is a result of the teaching strategies they employ, which may favour or hinder learning (Prieto, 2007). Teacher self-efficacy research concludes that it is associated with much of teachers' behaviour, including instructional planning, their alternative ideas about the scientific content (Jones & Carter, 2007), the importance they attach to active learning (Enochs et al., 1995), their control and discipline in the classroom (Jones & Carter, 2007), etc.

Attempts to reach a consensus on a precise definition of emotion have always proved controversial and unsuccessful, meeting with widespread disagreement among authors, so that there is still no definition of emotion that is accepted by all. The working definition taken by our research group is that given by Bisquerra (2000), who defines emotions as reactions to the information we receive in our relationships in the environment.

The relationship between self-efficacy and emotions was already recognized in the analyses that some authors made of these two constructs. For Saarni (2000), emotional competence is the demonstration of self-efficacy in expressing emotions in social transactions.

Self-efficacy is not constructed from scratch, but is founded on judgements about one's own abilities. Emotional states are among the major sources of self-efficacy. Indeed, people differ in how they interpret their emotional states, and these emotional states also influence their judgements on their own competences. Positive emotions increase perceived efficacy, and negative emotions reduce it (Salanova et al., 2005).

Recent studies have addressed the empirical study of some emotional states as sources of self-efficacy in secondary school teachers. Llorens et al. (2005) showed in a sample of teachers that there are two ways of predicting self-efficacy from emotional states. One is that the perception of positive emotions is related to experiencing greater job engagement, which in turn acts as a source of the teacher's self-efficacy. The other is that low levels of self-efficacy are preceded by high levels of negative emotions. The findings of Salanova et al. (2005) were similar. Ritchie et al. (2011), in a study of a novice science teacher, find that positive emotions are related to the achievement of positive expectations and with the failure of negative expectations to actually be fulfilled, while negative emotions are related to the failure to achieve positive expectations. Other work has also shown that certain negative emotions can act as mediators between self-efficacy and its facilitators or obstacles (García et al., 2006), indicating that the fact of experiencing a negative emotional state affects the levels of self-efficacy.

PURPOSE

The study had two objectives: to compare the emotions in teaching the Nature Sciences (biology and geology) and the Hard Sciences (physics and chemistry), and to analyze the relationship between beliefs in self-efficacy and the emotions that initial teacher education students see themselves as having as future teachers of Nature Sciences or the Hard Sciences.

METHODS AND SAMPLES

An exploratory, descriptive study was conducted by means of a survey presented to 188 first-year students of Primary Education with no experience as teachers at the Education Faculty of the University of Extremadura, belonging to the First Degree Course in Primary Education during the academic year 2009-10. The instrument used was a questionnaire organized into two blocks. One was a Likert-scale set of items on self-efficacy, with four items presented in the form of statements or judgements on the respondent's self-efficacy as future teachers. These items were based on two published questionnaires on the self-efficacy of prospective teachers – STEBI-B (Enochs & Riggs, 1990) and that of Uzuntiryaki & Capa Aydin (2009).

The other block was a table of emotions in which the participants were asked to mark which of the 24 emotions offered they believed they would experience as future primary science teachers, for both the Nature Sciences (Biology and Geology) and the Hard Sciences (Physics and Chemistry). These emotions were chosen following the proposals of Bisquerra (2009) and Damasio (2010), distinguishing between positive and negative emotions.

The resulting data were subjected to the necessary processes of checking, coding, and digital storage in order to proceed with their descriptive analysis using SPSS (Statistical Product and Service Solutions) 18.0.

RESULTS

Although there is only one science subject in primary education, we distinguished topics in the curriculum related to the hard sciences (Physics or Chemistry) and those related to the nature sciences (Biology or Geology) in order to explore what emotions the respondents believed they would experience in each of these areas. The reliability analysis of the emotions questionnaire gave a value of 0.835 for Cronbach's alpha, corresponding to a good level of reliability.

The results showed the prospective primary school teachers to have conflicting emotions about their future teaching of content related to the Nature Sciences as compared with those related to the Hard Sciences (Figure 1). For the Nature Sciences the predominant feelings were all positive (motivation, interest, curiosity, tranquillity, enthusiasm, etc.), while for the Hard Sciences the predominant feelings were all negative, with the highest percentages being reached for fear, tension, worry, nervousness, and distress. This result is consistent with previous studies of other samples of prospective primary teachers in their initial teacher education (Brígido et al., 2010).

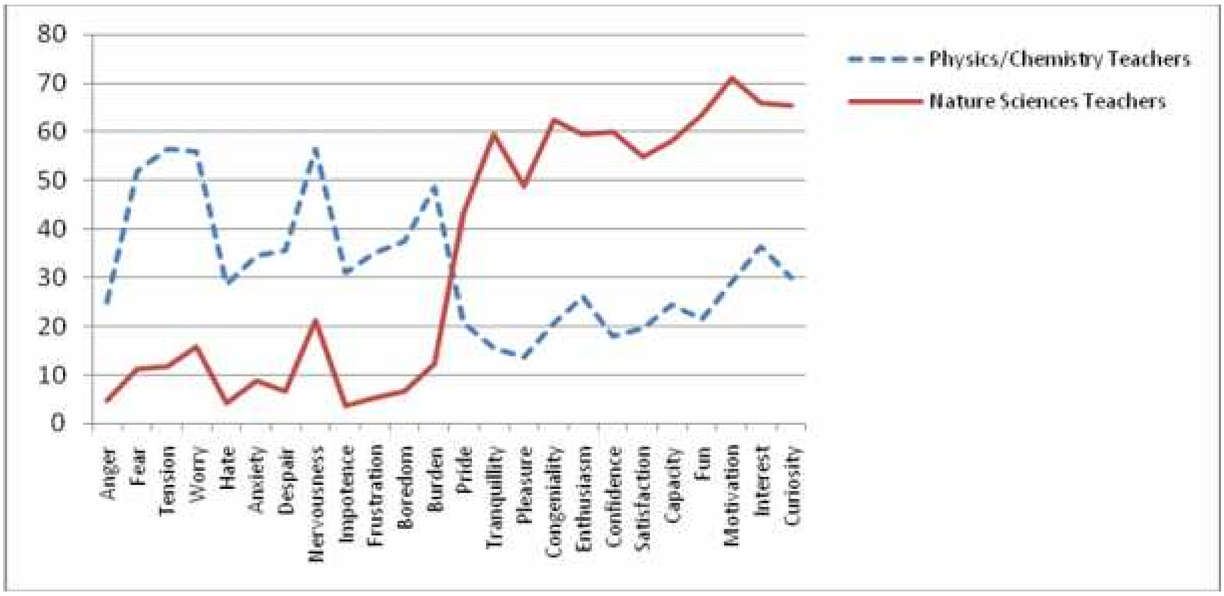

Figure 1. “Comparison of emotions in teaching Nature Sciences or the Hard Sciences”

The results indicated that the majority of respondents (67.4%) believed highly in their self-efficacy for their future science teaching. Relating this result with the emotions concerning Nature Sciences, we found few differences between respondents with high or low beliefs about their self-efficacy in the subject of Nature Sciences (Figure 2).

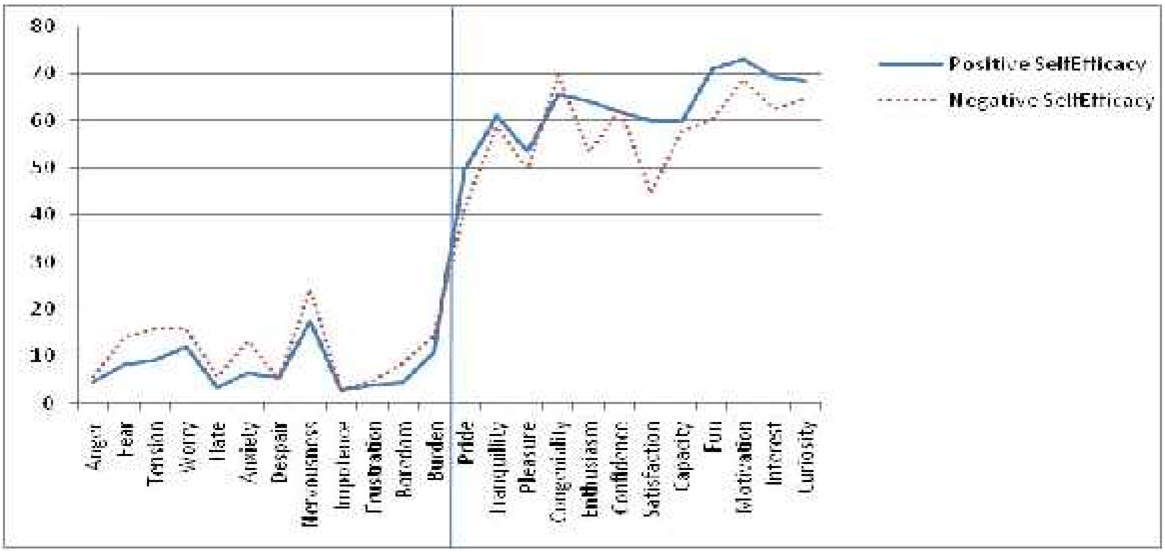

Figure 2. “Emotions in Nature Sciences according to beliefs concerning self-efficacy”

In the case of the Hard Sciences however (Figure 3), the prospective teachers with positive self-efficacy had more positive emotions and fewer negative emotions than those with negative self-efficacy.

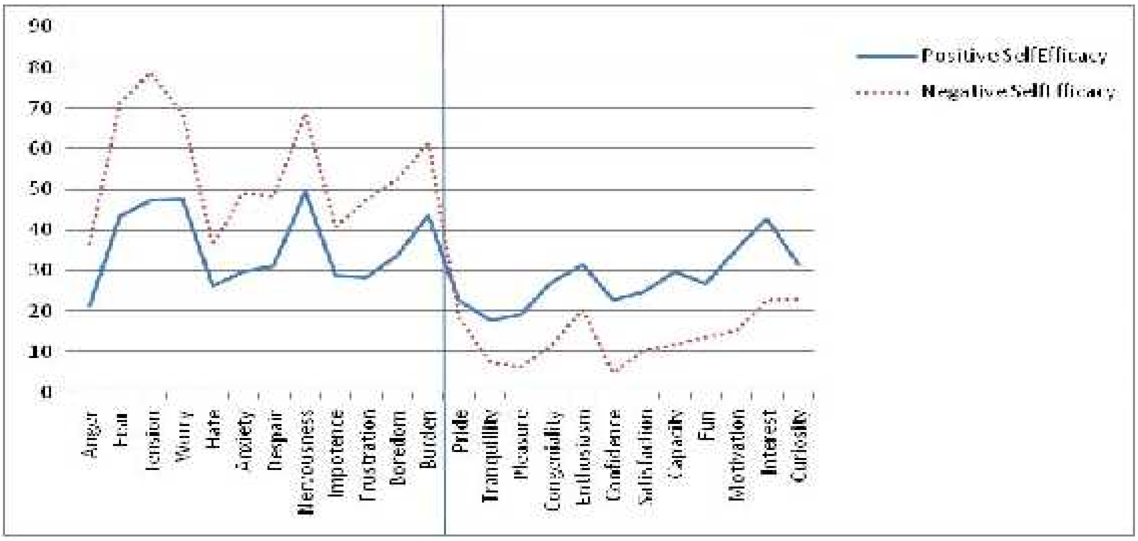

Figure 3. “Emotions in Hard Sciences according to beliefs concerning self-efficacy”

CONCLUSIONS AND IMPLICATIONS

The emotions of pre-service primary teachers in teaching depend on the scientific subject to be taught. In the Hard Sciences (physics and chemistry), the emotions are mostly negative, while in Nature Sciences (biology and geology) they are very positive.

Positive beliefs in self-efficacy in their future science teaching predominate over negative beliefs. There is little difference between the self-efficacy beliefs and the emotions in the future teaching of Nature Sciences. But teachers with positive self-efficacy beliefs also have more positive emotions and fewer negative emotions concerning the Hard Sciences than those who have negative self-efficacy.

With respect to the implications, we believe that the study of emotions is important in the context of initial teacher education. It can help them on the one hand to become aware of their own possible emotional vulnerability, of their time at school, and of how emotions affect teaching and learning the different science subjects, and on the other to develop the capacity to self-regulate those emotions. Younger teachers are more likely to incorporate educational changes into their practice, and to consider the emotional dimension of those changes (Hargreaves, 2005). It is therefore necessary to develop programs of intervention and emotional support for prospective teachers (Appleton, 2008, Koballa et al., 2008; Shoffner, 2009) in order for them to gain in emotional competence – an aspect on which we are currently working. The results of our study, together with other research, also suggest the need to include in teacher education programs strategies for the improvement of self-efficacy (Hoy & Spero, 2005), especially in subjects like Physics or Chemistry which show themselves to cause prospective primary teachers major cognitive and emotional difficulties.

PRE-SERVICE SCIENCE AND PRIMARY SCHOOL TEACHERS' PERCEPTIONS OF SCIENCE LABORATORY ENVIRONMENT

Gamze Çetinkaya[1] *and Jale Çakıroğlu*[1]
[1] Middle East Technical University

Abstract: The associations between students' perceptions of science laboratory environments, science achievement, and their attitudes towards science have been examined extensively in science education literature (Wong & Fraser, 1994; Hofstein, & Cohen, 1996; Lee & Fraser, 2001; Özkan, Çakıroğlu, & Tekkaya, 2008); however, there have been limited studies focusing on pre-service teachers' (PTs). The purpose of this study was to examine pre-service elementary science teachers' and primary school teachers' perceptions of science laboratory environment and to investigate its relationship with their achievement in science laboratory and attitudes towards science lessons. The differences in PTs' perceptions of laboratory environment by their major area were also investigated. Participants of this study were 178 PTs enrolled in science laboratory course in the departments of elementary science education and primary education. Data were collected through Science Laboratory Environment Inventory (Fraser, Giddings, & McRobbie, 1995) and Science Attitude Scale (SAS) (Geban, Ertepınar, Yılmaz, Altın, & Şahbaz, 1994). In order to investigate the relationship between participants' perceptions of science laboratory environments, their attitudes toward science lessons and their achievement in science laboratory, simple correlation analysis was used. MANOVA was also used to investigate the differences across departments. The findings indicated that most of the participants have high scores on SLEI subscales except Open-Endedness subscale (M=19.33, SD=3.62). Simple correlation analysis results showed that both achievement and attitude are positively related to Integration subscale of SLEI. Moreover, department has found to be a significant factor differentiating PTs' perceptions of laboratory environment in Student Cohesiveness and Material Environment subscales. Although this difference is statistically significant, there are not any major differences between mean scores of two groups. On the other hand, SAS mean scores of pre-service primary school and elementary science teachers were found to be significantly different. PTs majoring in science education have high positive attitudes toward science compared to pre-service primary school teachers.

Keywords: Science Laboratory, Pre-service Teachers, Science Education, Learning Environment, Attitude.

BACKGROUND, FRAMEWORK, AND PURPOSE

Science laboratory has a crucial role in science education as it gives students a chance to embody their theoretical knowledge. In the literature, there have been many studies investigating the relationship between students' perceptions of laboratory environments and students outcomes (e.g. Özkan, Çakıroğlu, & Tekkaya, 2008). Previous studies have consistently showed that there is a strong relationship between students' laboratory environment perceptions and their outcomes. The possible effects of other student characteristics such as gender, grade level, subject, school type were also investigated with different studies all around the world (e.g. Wong & Fraser, 1994).

The purpose of this study was to examine pre-service elementary science teachers' and primary school teachers' perceptions of science laboratory environment and to investigate its relationship with their achievement in science laboratory and attitudes towards science lessons. In this study, the differences in pre-service teachers' (PTs) perceptions of laboratory environment by their major area were also investigated. The following research questions guided the study:

1. Is there a relationship between PTs' perceptions of their science laboratory learning environment and their science laboratory achievement?
2. Is there a relationship between PTs' perceptions of their science laboratory learning environment and their attitudes toward science lessons?
3. Is there a significant difference in PTs' perceptions of their science laboratory learning environment and their attitudes toward science lessons by their departments?

RATIONALE

The associations between students' perceptions of science laboratory environments, science achievement, and their attitudes towards science have been examined extensively in science education literature (Wong & Fraser, 1994; Hofstein, & Cohen, 1996; Lee & Fraser, 2001; Özkan, Çakıroğlu, & Tekkaya, 2008). However, there have been limited studies focusing on pre-service teachers' perceptions of science laboratory environments. PTs' perceptions of the learning environment can give valuable information to improve the effectiveness of science laboratory in the teacher education programs. The effectiveness in science laboratory is very important for pre-service teachers because they will teach science and conduct laboratory applications in their future schools.

METHODS

Sample

The participants of this study were 178 pre-service teachers enrolled in science laboratory course in the departments of elementary science education and primary education at Sakarya University in Turkey. Of the 178 participants, 89 were 3th year students majoring in elementary science education (69 female, 20 male students) and 89 were 2th year students majoring in primary education (72 female, 17 male students). Although the students from different departments attend different science laboratory courses, the course content and objectives are very similar and also both of these two courses are offered by the department of elementary science education. They use the same laboratory for the courses and conduct very similar experiments. The aim of the both courses is to help PTs to gain the ability of designing and applying experiments for science lessons.

Instrumentation

The data were collected through Science Laboratory Environment Inventory (SLEI) and Science Attitude Scale (SAS). Both of the questionnaires were administered at the same time to the participants. The first instrument, the SLEI, used to investigate PTs' perceptions of science laboratory environment, was developed and validated by Fraser, Giddings, and McRobbie (1995) and adapted into Turkish by Özkan, Çakıroğlu, and Tekkaya (2008). This questionnaire consists of 35 items and 5 different subscales with 7 items in each subscale (Student Cohesiveness, Open-Endedness, Integration, Rule Clarity, and Material Environment). In the current study, the alpha reliability coefficients of the subscales were found to be range from .60 to .78 with a total scale reliability of .79.

The second instrument SAS was used to assess students' attitude toward science lessons, and developed by Geban, Ertepınar, Yılmaz, Altın, and Şahbaz (1994). In the current study, the Cronbach alpha coefficient of this 15 item 5-point Likert type scale was found to be .94.

Data Analysis

In order to investigate the relationship between participants' perceptions of science laboratory environments, their attitudes toward science lessons and their achievement in science laboratory, simple correlation analysis was used. For this analysis, PTs' course grades are used as science laboratory achievement variable. Moreover, Multivariate Analysis of Variance (MANOVA) was also used to investigate the differences across departments on five different subscales of SLEI and SAS.

RESULTS

Descriptive Statistics

Pre-service teachers' perceptions of their laboratory environment were described by their responses to the SLEI in its five subscales; Student Cohesiveness, Open-Endedness, Integration, Rule Clarity, and Material Environment. The results showed that PTs see their science laboratory environment positively, as indicated by mean scores for subscales ranging from 2.78 to 4.04 over 5 (Table 1). The highest mean score of all subscales was for the Student Cohesiveness subscale (M=4,04, SD=.48) suggesting that students perceived great cohesiveness in their laboratory and they were helpful and supportive of each other. The second highest mean score was for the Integration subscale (M=3.96, SD=.40), indicating that students thought their laboratory activities were related to their theoretical courses. The mean score for the Rule Clarity subscale (M=3.94, SD=.54) was also high, implying that rules for laboratory courses and experiments were clear enough and students knew what they were supposed to do or not to do in the laboratory. For the Material Environment subscale the mean value can be considered as moderate (M=3.71, SD=.54). This means materials in the laboratory were found as an adequate by the students. The lowest mean score of all subscales was for the Open-Endedness subscale (M=2.78, SD=.42) indicating that students perceived a close-ended approach for their laboratory activities.

Table 1: Mean Scores of Pre-service Teachers' on Five Subscales of SLEI

	Mean	SD
Student Cohesiveness	4.04	.48
Open-Endedness	2.78	.42
Rule Clarity	3.94	.54
Integration	3.96	.40
Material Environment	3.71	.54

Simple Correlations Results

Simple correlation analysis results (Table 2) revealed that among five subscales of SLEI only Integration subscale was significantly and positively related to science laboratory achievement and to attitude toward science lessons with small effect size. Correlation coefficients of .10, .30, and .50, are interpreted as small, medium, and large effect size respectively (Green, Salkind, & Akey, 2000).

Table 2: Simple correlations with SAS scores and science laboratory achievement

		Student Cohesiveness	Open Endedness	Integration	Rule Clarity	Material Environment
Science laboratory achievement	Pearson Correlation	-.076	-.010	.152(*)	-.004	-.009
	Effect Size	.07	.01	.15	.00	.00
Attitude toward science lessons	Pearson Correlation	-.077	-,062	.268(**)	.020	-.012
	Effect Size	.07	.06	.26	.02	.01

* Correlation is significant at the 0.05 level (2-tailed).
** Correlation is significant at the 0.01 level (2-tailed).

Multivariate Analysis of Variance Results

A one-way between-groups multivariate analysis of variance was performed to investigate the differences across departments on five different subscales of SLEI and SAS. Preliminary assumption testing was conducted to check for normality, linearity, singularity and homogeneity of variance-covariance matrices, with no serious violations noted. MANOVA results comparing pre-service primary school teachers and elementary science teachers revealed that there was a significant difference between them on the combined dependent variables: $F(6,171)=29.63$, $p=.000$; Wilks' Lambda=.49; partial eta squared=.51. When the results for the dependent variables were considered separately, the differences to reach statistical significance using a Bonferroni adjusted alpha level of .008 were on the Student Cohesiveness subscale, $F(1,176)=12.63$, $p=.000$, partial eta squared=0.067; on the Material Environment subscale, $F(1,176)=13.16$, $p=.000$, partial eta squared=0.070; and on the attitudes toward science lessons, $F(1,176)=125.93$, $p=.000$, partial eta squared=0.417. An inspection of the mean scores indicated that on Student Cohesiveness (SC) and Material Environment subscales (ME) pre-service primary school teachers have higher mean scores with small effect size, whereas pre-service elementary science teachers have higher science attitude mean scores with large effect size. Mean scores and % variance explained by department in Student Cohesiveness and Material Environment subscales and Science Attitude Scale are presented in Table 3.

Table 3: Mean scores and percentage variance explained by department

		SC	ME	Attitude
Pre-service elementary science teachers	Mean	27.67	25.09	59.61
Pre-service primary school teachers	Mean	29.37	27.07	44.49
	% variance explained	6.7	7.0	41.7

CONCLUSIONS AND IMPLICATIONS

The findings of this study indicated that most of the participants have high scores on SLEI subscales except Open-Endedness subscale (M=19.33, SD=3.62). It can be concluded that although participants see their science laboratory environment positively, they think laboratory activities are close-ended. This finding is consistent with previous studies conducted with elementary and high school students (e.g. Lee & Fraser, 2001). This may be because experiments and their procedures are determined for students, they just follow the given guidelines and neither instructors nor students try to change this system in Turkey (Çakıroğlu, Telli, & Çakıroğlu, 2003). However, an open-ended approach might be more helpful to future teachers to find their own way to teach science and conduct laboratory experiments. Moreover, if pre-service teachers do not receive an open-ended instruction, they cannot be expected to be an innovative teacher in the future.

Simple correlation analysis results showed that both science laboratory achievement and attitude toward science lessons are positively related to Integration subscale of SLEI. Students who perceive greater integration between theoretical courses and laboratory applications have more positive attitudes toward science lessons and perform better in science laboratory courses. This finding is consistent with previous studies (e.g. Özkan, Çakıroğlu, & Tekkaya, 2008). Moreover, as the integration between theoretical courses and laboratory applications increases, students’ chance to embody their theoretical knowledge also increases and then they perform better and gain a more meaningful understanding.

In this study, department has found to be a significant factor differentiating students’ perceptions of laboratory environment in Student Cohesiveness and Material Environment subscales. Although this difference is statistically significant, there are not any major differences between mean scores of two groups. On the other hand, the significant difference between SAS mean scores of pre-service primary school and elementary science teachers is found. PTs majoring in science education have high positive attitudes toward science compared to pre-service primary school teachers.

Future research may be conducted to investigate the reasons of differences on attitude towards and achievement in science laboratory courses between primary education students and science education students and its influences in science education. Primary education PTs and science education PTs may be compared in terms of their pedagogical content knowledge level of science laboratory courses.

CONCEPTIONS OF PROSPECTIVE TEACHERS ON NATURE FIELD TRIPS IN RELATION TO OWN EXPERIENCES AS PUPILS

Emilio Costillo[1]*, Florentina Cañada*[1]*; Carmen Conde*[1] *and Javier Cubero*[1]
[1]Dpto. Didáctica de las Ciencias Experimentales y de las Matemáticas. Universidad de Extremadura. Av. de Elvas, s/n. 06011 Badajoz (Spain). Corresponding author: costillo@unex.es

Abstract: Numerous studies have shown that the nature field trips are a very important activity for pupils in the teaching and learning of Biology and Geology. But little research has been done on the specific knowledge of teachers concerning these activities, and even less has focused on prospective teachers. The present study was thus an exploratory analysis of the importance prospective teachers attach to nature field trips, examining whether their experiences with these activities while they themselves were pupils had any bearing on their conceptions as future teachers. We designed a questionnaire that was completed by 35 prospective secondary education teachers. These pre-service teachers were very much in agreement with the importance of these activities in enhancing their pupils' motivation and performance, and that these trips have an essential role to play in the teaching and learning of these subjects. Nonetheless, they did not value these activities equally highly in their own experience as pupils at school, and for many of them such field trips had been of no great importance in their learning these subjects. No relationship was found between their poor experiences in this sense as pupils and their views as teachers. The study thus points to an important issue in that the prospective teachers' expectations with respect to nature field trips may not be translated into any positive effect on their pupils' learning.

Keywords: Science field trip; Teacher development; Teaching and learning activities; Pædagogical Content Knowledge; affective domain.

Acknowledgements: This work was financed by Research Project EDU2009-12864 of the Ministry of Science and Innovation (Spain) and the European Regional Development Fund (ERDF).

BACKGROUND, FRAMEWORK, AND PURPOSE

Numerous studies have shown that nature field trips have a positive effect on pupils in both cognitive and attitudinal aspects (Falk, 1983; Bitgood, 1989; Rudman, 1994; Meredith et al., 1997). Most have focused on the pupils, and have described key aspects of these teaching-learning activities (Michie, 1998) together with their great complexity (Hurley, 2006). However, few have been directed at considering the specific knowledge that teachers use in these activities as a part of their overall pædagogical content knowledge (Shulman, 1986). This lack of information is even more patent with respect to initial teacher education. Indeed, one knows none of the aspects related to the cognitive and emotional domain of prospective teachers with respect to pupils' nature field trips, even though studies have found that such activities are fundamental to the education of teachers of biology, contributing to their construction of biological knowledge and pædagogical content knowledge, and fostering their reflection on their career as teachers (Amortegui et al., 2010). Besides the knowledge concerning nature field trips that teachers acquire at this stage of their education, prospective teachers have already accumulated information and attitudes about this activity as a result of their own experience as pupils as part of their continuous evolution from school age to their eventual professional development (Porlán et al., 2010).

RATIONALE

The aim was to make an exploratory analysis of the importance that prospective Biology and Geology teachers attach to nature field trips in the teaching and learning process of these subjects, and to inquire into their own experiences at school in these activities, and whether these experiences had any influence on their conceptions as future teachers.

METHODS

A specific questionnaire was designed (see Table 1) which was completed on a voluntary and anonymous basis during the 2009-10 academic year by 35 prospective teachers doing the Master's degree course in Secondary Teacher Education at the University of Extremadura in the speciality of Biology and Geology. A Spearman correlation analysis was performed to determine whether their present conceptions about nature field trips had any relationship with their own experiences as pupils in these activities.

Respond to the following statements with an X indicating which option you consider most closely expresses your degree of agreement. The scale is from 1 to 10, where 1 represents the greatest degree of disagreement.											
		1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
As Teacher											
Item 1	The importance of nature field trips has to do with increased motivation.										
Item 2	The effort in time, money, and material is rewarded by improved teaching and learning due to nature field trips.										
Item 3	The function of these nature field trips in learning concepts is not essential.										
As Pupil											
Item 4	They increased my motivation towards topics related to Biology and/or Geology.										
Item 5	They served mainly as a recreational activity rather than as something educational.										
Item 6	They meant a major improvement in my process of learning science.										

Table 1: Questionnaire used in the study.

RESULTS

The prospective teachers believed that nature field trips are very important in teaching and learning Biology and Geology (Figure 1). The vast majority of them see these activities as playing a key role in motivating pupils in these subjects: the median of their responses to Item

1 ("*The importance of nature field trips has to do with increased motivation*") was 9 (mean 8.97 ± 1.25, n = 35).They were also very much in agreement with the effect of these trips in improving their pupils' learning process: the median of their responses to Item 2 ("*The effort in time, money, and material is rewarded by improved teaching and learning due to nature field trips*") was 8 (mean 8.15 ± 1.40, n = 34).

Finally, they saw these activities as playing an essential part in pupils' learning: the median of their responses to Item 3 ("*The function of these nature field trips in learning concepts is not essential*") was 3 (mean 3.23 ± 2.20, n = 35). Nonetheless, their responses to Items 2 and 3, especially to the latter, reflected a certain disagreement among the prospective teachers (Figure 1).

Figure 1: Responses as future teachers to the questionnaire on nature field trips.

Their views as future teachers about nature field trips were different from their experiences as pupils (Figure 2). With respect to motivation towards Biology and Geology when they were pupils, most were in agreement that this had been enhanced by the field trips, although there was not the same uniformity of opinion as when they viewed these activities from a teaching standpoint (Figure 2). The median of their responses to Item 4 ("*They increased my motivation towards topics related to Biology and/or Geology*") was 8 (mean 7.03 ± 2.77, n = 34).

With respect to the importance of these activities, the prospective teachers did not see them as having had any great relevance in their experiences as pupils. For many of the respondents, these nature field trips played a recreational rather than an educational role: the median of their responses to Item 5 ("*They served mainly as a recreational activity rather than as something educational*") was 6 (mean 6.09 ± 2.08, n = 35). Although most of the respondents recalled these trips as helping to improve the learning process, this was not the case for a significant fraction of them. The median of their responses to Item 6 ("*They meant a major improvement in my process of learning science*") was 8 (mean 7.57 ± 2.06, n = 35). No statistically significant correlation was found between their responses corresponding to their views as future teachers and those corresponding to their experience as pupils.

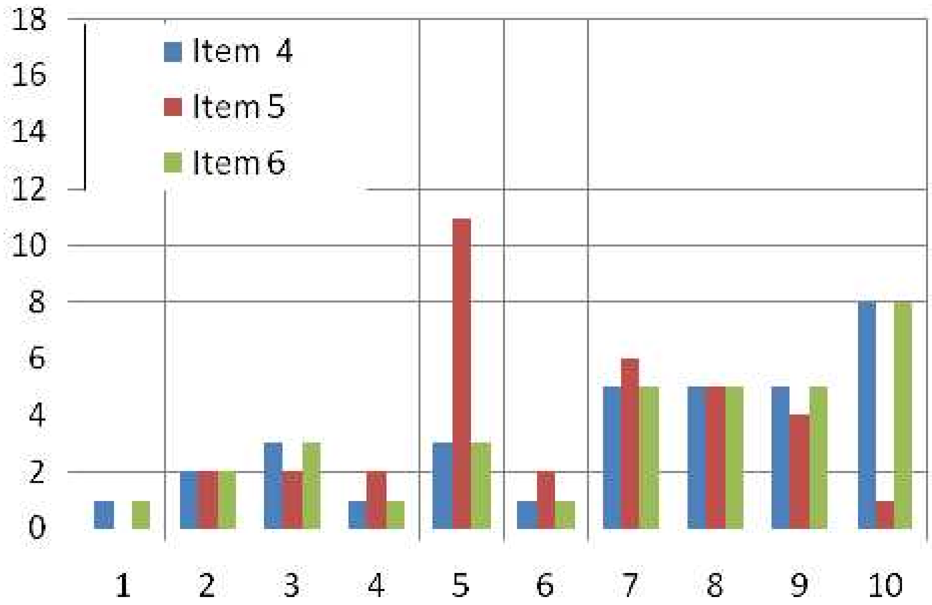

Figure 2: Responses regarding their own experience as pupils to the questionnaire on nature field trips.

CONCLUSIONS AND IMPLICATIONS

The prospective teachers agreed that nature field trips are an important activity in teaching and learning biology. In particular, there was strong agreement with:

(i) The relevance of these activities in enhancing the motivation of their pupils

(ii) The result for the pupil despite the effort involved in preparation.

(iii) Their essential role in the teaching and learning of Biology and Geology.

However, the respondents did not equally value these activities in recalling their own experience at school, and for many of the respondents nature field trips had been of no great relevance to their learning these subjects. The correlation analysis of these situations found no relationship between these expressions of poor nature field trip experiences as pupils and their consideration as future teachers. This may have been due to the reduced sample size, or to the teacher education process being followed by these prospective teachers which may in some cases have served to redress their unsatisfactory experiences as pupils.

The study has highlighted an important issue with respect to nature field trips in the teaching and learning of Biology and Geology. This concerns the potential mismatch that may arise between a teacher's expectations about the effectiveness of nature field trips and their actual positive influence on the pupils' learning (Figure 3). Further studies are therefore needed to analyze these situations, promoting actions that enable these activities to meet the expectations of the teachers who plan them, and to improve the learning process of the pupils. In this sense, an essential tool may be metacognitive programs of action research (Mellado et al., 2009).

Abstract: To create science lesson plans, teachers need to have not only science content knowledge and skills, but also ability to structure a curriculum and identify appropriate teaching methods and strategies to make the content comprehensible to students. Teachers also need the ability to identify expected students' actions and questions and to identify and incorporate 'how to respond to them' into the lesson plan. This study developed a case method program by using the *manga* textbooks for developing teachers' skills to create lesson plans. The program's effectiveness was evaluated through questionnaire surveys to program participants. From the results, this program was judged to be effective in developing the ability to create lesson plans.

Keywords: teacher education, case method, *manga*, lesson plan, science

1. INTORODUCTION

Fostering the next generation of teachers and developing their specialized knowledge, skills and competencies are major issues in teacher education. With regard to teachers' skills and competencies, the concept of pedagogical content knowledge (PCK) is widely known and has been extensively researched (e.g., Gess-Newsome & Lederman, 1999; Mishra & Koeher, 2006). Authors (2010) developed *manga* textbooks with a narrative approach to develop science teachers' skills and competencies, and evaluated the effectiveness of using those textbooks by conducting a survey with college students studying to become teachers. By using the *manga* textbooks developed by our project team, this study developed a case method program for developing teachers' skills to create lesson plans—the essential teacher skill of developing and conducting a lesson, and then evaluated the effectiveness of the program. The program's effectiveness was evaluated through questionnaire surveys to program participants, i.e., college students studying to become teachers. The evaluation was conducted from the following two perspectives: (1) college students' perceptions of the usefulness of the program, and (2) whether or not college students were able to create a lesson plan, giving enough consideration to children's expected actions and responses in the classroom.

2. THEORITICAL GROUND FOR THE USE OF *MANGA*

The theoretical grounds for using *manga* textbooks as a learning tool lie in the characteristics of *manga* as a medium; *manga* can be read and assimilated in a relatively short period of time, and messages to which the author wants to draw readers' attention can be embedded in pictures and words. Yoshikawa (2007) used *manga* textbooks with a narrative approach in MBA and other training programs in the field of business administration, and proved that *manga* textbooks are effective for developing learners' abilities to apply knowledge and skills to new contexts and in judging situations accurately. Yoshikawa suggested the possibility that *manga* textbooks can be used in various areas other than business, by adhering to the following six rules. The *manga* textbook developed in this study follows these six rules.

① Create an "event" in each scene that illustrates a key learning point.
② Embed pieces of information in a way that inspires readers to think about the event.
③ Create a context-dependent scenario, by establishing connections between an event and other events that had happened before that particular event.
④ Determine a theme for group discussion beforehand.
⑤ Create a focus point in each picture.
⑥ Determine what information should be expressed through words, what information should be embedded in pictures, and what information can be left implicit.

3. THE CASE METHID PROGRAM FOR TEACHER EDUCATION

To create science lesson plans, teachers need to have not only science content knowledge and skills, but also ability to structure a curriculum and identify appropriate teaching methods and strategies to make the content comprehensible to students. Teachers also need the ability to identify expected students' actions and questions and to identify and incorporate 'how to respond to them' into the lesson plan. However, the development of these skills and abilities cannot happen overnight; most of these skills/abilities are gained through experience.

The case method program for teacher education developed in this study is designed to enable users to simulate the execution of a lesson through a *manga* textbook that depicts, in a narrative way, actions and behaviors that students may perform during the lesson, and safety issues that relate to the lesson content. The topic of the lesson covered in the *manga* textbook

Figure 1.
Example of the manga textbook

used in this study was "how to operate a manual electric generator," which is covered in the lesson unit on energy (Figure 1). Problems embedded in the *manga* textbook were: 5 instruction-related problems, 3 problems with experimental techniques, and 4 lesson environment-related problems. Through this program, learners can develop their ability to accurately judge a situation, by engaging in solving problems as a main character of the story.

4. EVALUATION METHODS

The program's effectiveness was ev aluated from the following two per spectives:

(1) College students' perceptions of the usefulness of the program: A survey was conducted in April 2010 with 74 students of a women's college in Kyoto Prefecture who are studying to become teachers. After completing the program, the students answered a 4-point Likert scale questionnaire and a free response questionnaire. The Likert scale questionnaire contained a total of 14 items: 10 items regarding the effectiveness of the use of the manga textbook in learning how to develop a lesson plan, and 4 items regarding college students' impressions about the use of a manga textbook.

(2) Whether or not college students are able to create a lesson plan, giving enough consideration to children's expected actions and responses in the classroom: A study was conducted in August 2010 with 12 students of a national university in Hyogo Prefecture who are studying to become teachers. First, the college students were instructed to develop a lesson plan for a science lesson on a given topic (the topic covered in the manga textbook). Then they studied the manga textbook. After that, they made additions and corrections to the lesson plan they had created beforehand. By focusing on whether the college students gave enough consideration to expected children's actions and responses in the classroom, we examined "in which sections additions or corrections

were made" and "the contents of the additions/corrections made," from the three perspectives of instruction, experimental techniques, and lesson environment.

5. RESULTS AND DISCUSSION

From analysis of the results of the questionnaire regarding the program's usefulness (Table 1), it was found that all items received positive responses, which was statistically significant (p<.01).

Regarding sections of the lesson plan to which additions/corrections had been made (Table 2), most of the additions/corrections were made in the section of "important points for teaching" Analysis was also performed on the numbers of college students who made or did not make additions/corrections by perspective, using the direct probability calculation method. As a result, statistically significant differences were observed regarding instruction and experimental techniques (p<.05); no statistically significant differences were found regarding lesson environment (*n,s*). Judging collectively from these results, it can be concluded that college students recognized the importance of the ability to predict children's difficulties and possible actions in preparing a lesson plan, as well as the necessity of acquiring good teaching and experimental skills.

Table 1. Questionnaire items and results

	Item	Students who aim to become elementary school teachers		
		YES	NO	
1	This textbook enables effective learning of lesson plan development.	74	0	**
2	This textbook is easy to use, and explanation in the textbook is easy to understand.	72	2	**
3	The instructional method that engages learners in group discussion, using a textbook, was effective.	74	0	**
4	This textbook is useful for individuals aiming to become teachers.	74	0	**
5	I could understand the relationship between the organization of the lesson plan and the lesson.	72	2	**
6	I understood the difficulty of executing the lesson as planned.	74	0	**
7	I understood the importance of the lesson plan for effective teaching.	74	0	**

8	The textbook was useful for me to understand how to write a lesson plan.	73	1	**
9	I understood how to read a lesson plan.	73	1	**
10	I understood that the lesson plan is an effective tool for communicating the lesson content and teaching methods used in the lesson.	74	0	**
11	I understood that it is important to create a lesson plan, predicting what will happen during the lesson.	74	0	**
12	To create a lesson plan, it is necessary to understand pupils' attitudes and learning abilities.	74	0	**
13	I think that this learning experience will be of help in creating lesson plans in the future.	74	0	**
14	I want to read a *manga* textbook that deals with lesson plan development, if it exists.	74	0	**

Table 2. Modified parts of the lesson plan

	Added and corrected sections			Added and corrected perspectives		
	Lesson content	Student activities	Important points for teaching	Instruction	Experimental techniques	Lesson environment
Total	1	3	12	11	10	8

6. FUTRE TASKS

This program was judged to be effective in developing the ability to create lesson pla ns. The plan is to develop more case method programs to accommodate learners' vary ing levels of lesson plan development skills and to conduct surveys to investigate the effectiveness of the developed programs.

JORDANIAN CHEMISTRY STUDENT TEACHERS' AND EXPERIENCED TEACHERS' BELIEFS ABOUT TEACHING AND LEARNING

Ingo Eilks, Siham A. Al-Amoush[1] and Silvija Markic[1]

[1]University of Bremen, Germany

Abstract: This poster presents an exploratory study of Jordanian chemistry student teachers` and experienced teachers' beliefs about teaching and learning. As method we used teachers' and students' drawings of teaching situations accompanied by four open questions. Data was evaluated by a grid describing teachers' Beliefs about Classroom Organization, Beliefs about Teaching Objectives and Epistemological Beliefs. For validation, a second evaluation using the same data source is made by applying the 'Draw-A-Science-Teacher-Teaching'-Checklist (DASTT-C), which shows the teacher- or student-centeredness of teachers` beliefs concerning science teaching. The results indicate that both above-mentioned groups hold quite traditional beliefs, which are teacher- and content-centered when it comes to chemistry teaching practices. Student teachers profess ideas which are even more pronouncedly traditional.

Keywords: chemistry education, teachers' beliefs, DASTT-C

FRAMEWORK AND OBJECTIVES

Teachers´ beliefs have recently gained increased attention in both general educational research (Munby, Russell & Martin, 2001) and in science education (De Jong, 2007). Studies focusing on both in-service (Woolley, Benjamin, & Woolley, 2004) and pre-service teachers (Bryan, 2003; Richardson, 2003). Such studies provide promising approaches to better understanding teachers' learning processes and behavior in class (Nespor, 1987). Evidence of student teachers' beliefs is also valuable for teacher trainers, who can map out currently-held ideas about teaching and learning, then see how they can be applied and/or changed (Nisbett, 1980). Such knowledge shows potential for improving university teacher education programs in order to better facilitate candidates' personal learning and professional development (Bryan, 2003). Finally, research on beliefs is seen as useful for curriculum innovators and planners, who can more effectively implement curriculum changes by taking existing teachers` beliefs into consideration (De Jong, Veal & Van Driel, 2002).

From previous research we know that different factors influence and shape existing teachers` beliefs, including teacher's own learning experiences in school, educational background, the quality of pre-service experiences in class, opportunities for self-reflection (or the lack theory) during pre-service training, and the influence of discipline-related and domain-specific subject matter training (Goodman, 1988; Markic & Eilks, 2008). The larger context of national policies and the context of cultural norms and values also play an important role in affecting teachers` beliefs (Isikoglu, Basturk & Karaca, 2009). Markic and Eilks (2008) have demonstrated the influence of educational domain and the level of education on the formation of educational beliefs. In their study on freshman student teachers in Germany, primary school science and secondary biology teacher trainees showed themselves to be very student-centered in their beliefs and approaches. Their colleagues with a comparable educational and cultural background preparing to teach secondary school chemistry and physics proved to be much more teacher-centered, holding extremely content structure-driven beliefs.

Increasing numbers of studies about teachers' beliefs are now being published. Starting from trainees' general educational beliefs, Van Driel, Bulte and Verloop (2007) were able to distinguish between two different ideologies which form a continuous dimension visible within various beliefs studies. The first ideology has been called *teacher-centered* (Bramald, Hardman, & Leat, 1995) or, alternately, *subject-matter oriented* (Billig, Condor, Edwards, Gane & Middleton, 1988). On the opposite end of the spectrum we find the *personal* (Shen, 1997), also called *student-supported* (Trigwell, Posser, & Taylor, 1994) or *learner-centered* (Bramald et al., 1995) learning. Markic and Eilks (2008) suggest viewing this spectrum as a range between traditional beliefs (transmission-oriented beliefs of learning with a focus on pure subject-matter knowledge) and modern beliefs (beliefs based on constructivistic learning, student-oriented classroom structures, and an orientation on more general educational skills, including Scientific Literacy for all). This dichotomy is in line with e.g. Thomas, Pederson and Finson (2001) or Van Driel et al. (2007), or Qablan, Jaradat and Al-Momani (2010) for curriculum reform in Jordan what is the background of this study. Unfortunately, evidence concerning secondary chemistry (student) teachers' beliefs about teaching and learning in Jordan is scarce in the literature.

Currently, the country of Jordan is going to great efforts to develop and expand its educational system (Jordan Ministry of Education, 2010). Many reforms have already been elaborated upon and tested. However, teachers' beliefs are not included in the focus of these innovations, whose implementation remains unsatisfactory (Qablan et al. 2010). The purpose of the current study was, therefore, to investigate different aspects of chemistry (student) teachers` beliefs about secondary chemistry in order to pinpoint any differences between Jordanian in-service and pre-service teachers. The focal points selected were quite general. They dealt primarily with achieving a general overview of chemistry teachers' beliefs about teaching and learning, the aims and objectives of chemistry lessons, and classroom culture and activities.

This study attempts to answer the following questions:

1. What beliefs do Jordanian teacher trainees and in-service teachers hold regarding chemistry teaching and learning, including student- and teacher-centeredness, overall teaching objectives, and understanding the learning process?
2. What are the similarities and/or differences in beliefs about teaching and learning for these two groups regarding the above-mentioned fields?

METHOD AND SAMPLE

The study is based on a modified version of the "Draw-A-Science-Teacher-Test Checklist" (DASTT-C). The original DASTT-C (Thomas, Pedersen & Finson, 2000; 2001) requests the participant to draw oneself and the learners in a typical classroom situation. The drawing is followed up by two open-ended questions about the activities of teacher and students. Markic, Eilks, and Valanides (2008) added another two open-ended questions to this to gain a more detailed overview of the situation. The added questions inquire into the teaching and learning objectives of the situation depicted and the approach chosen towards the drawn situation.

A first evaluation was done by an evaluation grid developed by Markic et al. (2008). This grid categorizes a range stretching from traditional beliefs to more modern beliefs in line with current educational theory. The evaluation pattern analyzes participants` beliefs in three qualitative categories: 1) *Beliefs about Classroom Organization*, 2) *Beliefs about Teaching Objectives*, and 3) *Epistemological Beliefs*. Each category was evaluated using a range from -

2 to +2 to describe beliefs in the above-mentioned dimensions along an ordinary, but non-linear scale (Markic et al., 2008). Data was encoded by two independent raters. The agreement rate was continuously above 80%. In cases of disagreement, joint rating was carried out by searching for inter-subjective agreement (Swanborn, 1996).

Table 1: An overview of the scales in the qualitative part of the study (Markic & Eilks, 2008)

	Traditional beliefs		*Modern beliefs*
Beliefs About Classroom Organization	Classroom activities are mostly teacher-centered, -directed, -controlled and dominated by the teacher.	↔ -2, -1, 0, 1, 2	Classes are dominated by student activity and students are (at least partially) able to choose and control their activities.
Beliefs About Teaching Objectives	The focus of science teaching is more-or-less exclusively focused on content learning.	↔ -2, -1, 0, 1, 2	Learning of competencies, problem solving or thinking in relevant contexts are the main focus of teaching.
Epistemological Beliefs	Learning is passive, top-down and controlled by the dissemination of knowledge.	↔ -2, -1, 0, 1, 2	Learning is a constructivistic, autonomous and self-directed activity.

For validation, this study also applied the original pattern from the “Draw-A-Science-Teacher-Test Checklist” (DASTT-C) by Thomas et al. (2000; 2001). In DASTT-C, the drawings and open-ended questions are evaluated using a checklist. The total score depends on the presence or absence of thirteen attributes in three main areas: the teacher, the students, and the environment. The complete checklist can be found in Thomas et al. (2000). The presence of any of the thirteen attributes within a section is scored with a "1", an absence with "0". Thus, the total score can fall between 0 and 13. Scores of 0-4 indicate student-centered teaching, while values between 7 and 13 represent teacher-centeredness, no decision is made for scores of 5 or 6 (Thomas et al., 2000). The data was rated by two independent raters; inter-rater reliability was moderately high ($\kappa = 0.74$ for teachers and $\kappa = 0.76$ for student teachers).

The sample consisted of 23 student teachers (13 male and 10 female) and 44experience teachers (25male and 19 female).

RESULTS AND DISCUSSION

Examples from the sample are given in Figure 1. Figure 3a represents an example of teacher-centered beliefs. The teacher in Figure 3a appears in the center of classroom activity. The students are either responding to the teacher by answering his questions or simply listening to him; the blackboard is the focus of all student attention. This classroom is a traditional one without any indicators of student activity (experimental equipment, etc.). The drawing in Figure 3b gives a student-centered viewpoint showing students in the lab performing an experiment. Typical teacher-centered indicators are not present, for example, the teacher standing in the center of the classroom or media centralizing the students’ attention.

In the first data interpretation (Figure 2) the *Beliefs about Classroom Organization* show strong tendencies towards teacher-centered beliefs can be recognized in both groups. Over 90% of the student teachers and almost 80% of experienced teachers described a classroom dominated by the teacher, where student activity plays only a minor role and is completely dominated by the teacher. The same can be said for *Beliefs about Teaching Objectives*. A dominant majority (about 80%) of student teachers expressed traditional beliefs about the objectives of chemistry lessons. The more-or-less exclusive goal of chemistry lessons in their estimation is the learning of subject-matter content. This is in line with Qablan et al. (2010), whose findings described Jordanian primary school teachers' attitudes towards educational reform who discussed reforms primarily by referring to developments in more effective methods of pure knowledge transfer. The same can be said for the group of in-service chemistry teachers in the present study as well. By the number this group is being a bit less extreme but the tendency towards the most strongly traditional beliefs was more pronounced in a group as a whole. For *Epistemological Beliefs* both groups draw situations with chemistry teaching being quite strongly as a transmission of knowledge organized by the teacher (scores “-2” and “-1”). About 70% of the student teachers expressed strong traditional beliefs about teaching (score “-2”). The in-service teachers were not as traditional as the student teachers in this regard. The majority received a score of “-1” in this category, which can be interpreted as being "rather transmission-oriented". No student teacher professed beliefs which could be rated as either modern or quite modern; even among experienced teachers there were only about 5% (scores “2” and “1”) of participants who expressed relatively modern ideas.

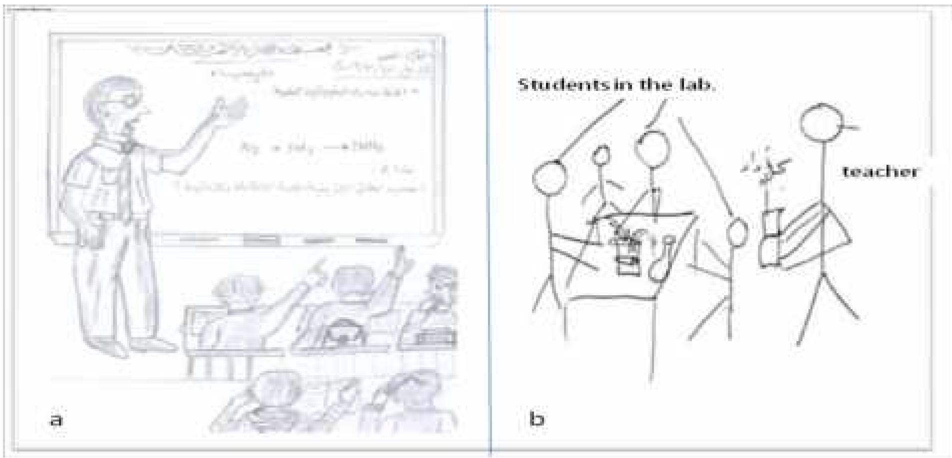

Figure 1. (a) Traditional/teacher-centered and (b) modern/student-centered drawings of two Jordanian teachers

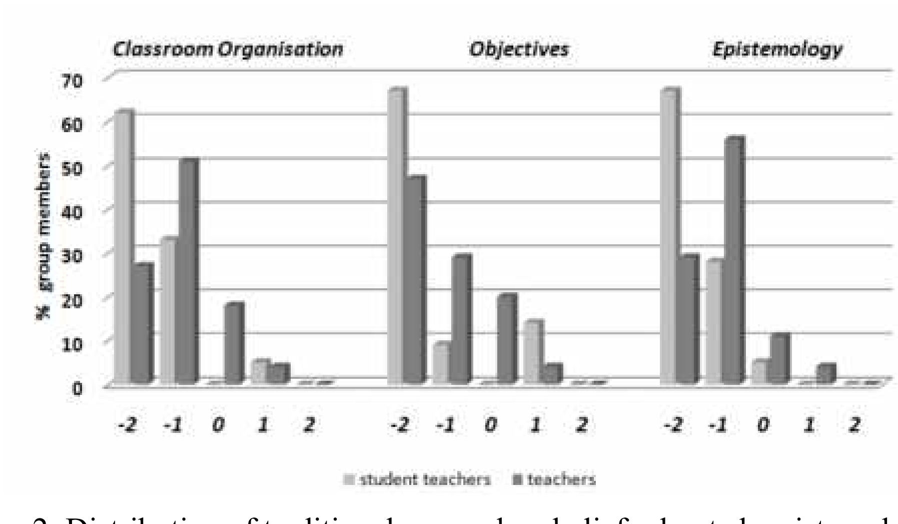

Figure 2: Distribution of traditional vs. modern beliefs about chemistry education

If a teacher has similar replies in each of the three categories, the combination of codes will appear on or near the diagonal stretching from (-2/-2/-2) to (2/2/2) (Markic & Eilks, 2008). The closer a given code combination comes to the upper, right, back part of the 3D-diagram, the closer these beliefs are to modern educational theory. Conversely, code combinations appearing in the lower, left, front part of a 3D-diagram represent more traditional beliefs. Jordanian student teachers in general hold very traditional beliefs. The ideas expressed by experienced, in-service chemistry teachers show more scattering, but also evidence a tendency towards more traditional beliefs. Both groups professed more-or-less strongly teacher-centered, content-structure, and transmission-oriented beliefs (Figure 3).

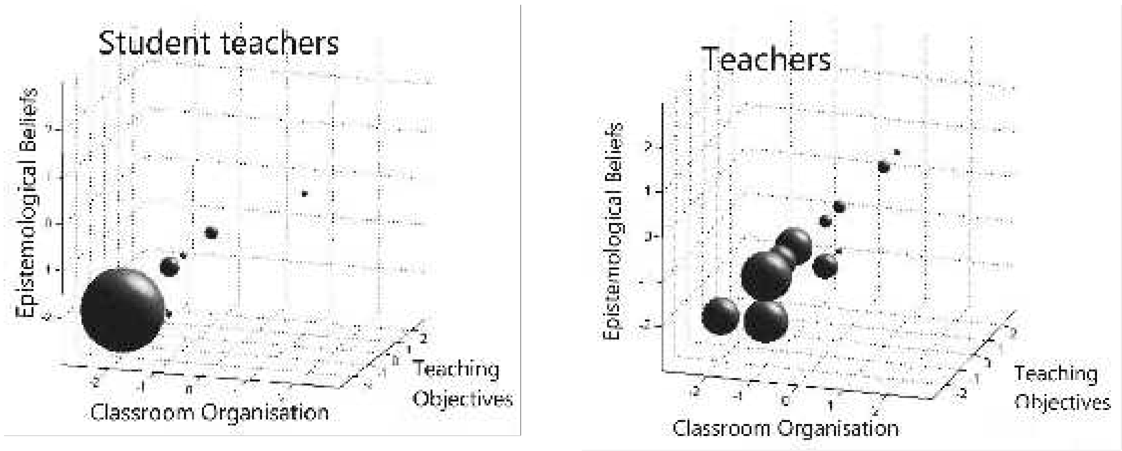

Figure 3: 3D-representation of the data

Figure 4 present the validating results of applying the checklist from Thomas et al. (2001). Also here teachers and student teacher both hold predominantly teacher-centered beliefs. 87% of student teachers fall into the teacher-centered area (a score of 7-13). The majority of experienced teachers also achieved scores of 7-13, but this group is 70% smaller than that of the student teachers. Only 4% of student teachers and 16% of the in-service teachers attained a score which characterized them as being student-centered.

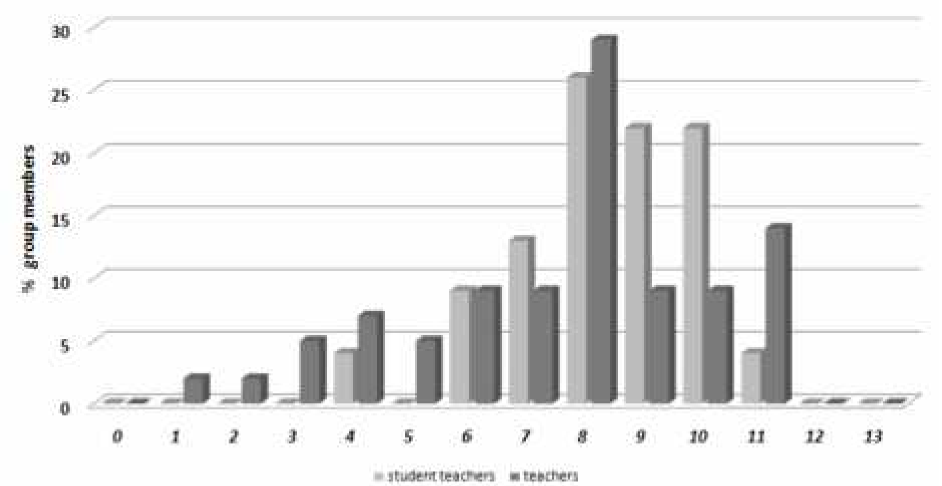

Figure 4. Distribution of student and in-service teachers according to DASTT-C

CONCLUSIONS

Both Jordanian in-service teachers and student teachers hold very traditional beliefs when it comes to teaching and learning chemistry. Such traditional beliefs can be characterized by teacher-centeredness, a transmission-oriented understanding of learning, and a strong focus on the pure learning of subject-matter. A second observation is that student teachers' beliefs tend to be much more traditional than those of experienced teachers. This might stem from the fact that Jordanian chemistry teachers attend only a workshop-based training program, and having no long-term based practice oriented courses during teacher education.

Nevertheless, beliefs and ideas expressed about chemistry teaching practice still remain very traditional. Only in rare instances are they connected with modern, theory-driven characteristics of chemistry education. Reasons for this might include the lack of appropriate in-service training in Jordan, the content level of courses offered, the amount of total training available and an extremely short training duration of only one year. Strongly bottom-up teacher training programs, e.g. those found in Germany, have already shown that substantial and sustainable changes are possible in the long run by combining educational courses with domain-specific education (Markic & Eilks, 2011). Another important consideration is that nearly all of the student teachers expressed very strong, traditional beliefs. These beliefs have mainly been constructed due to their previous experience as learners in school and university. This yields a picture of the prevalent practices in the Jordanian educational system which demands more self-reflection on these practices using the lens of modern educational theory.

The situation described here demands innovations in teacher training. This falls in line with Oliamat (2009), who recommended a more thorough concentration on the elaboration of teacher training programs to develop both teachers' pedagogical knowledge and teaching practices. Systems and structures are notoriously hard to change. Perhaps it would be easier and more effective to simply change the content within already existing courses. The workshops should be optimized to more thoroughly content prospective teachers with concrete student-active methods, instructional tools and illustrating examples for the domain-specific learning environments they later on will work in. But the teachers and student teachers also need tools and competencies to reflect upon teaching objectives in the sense of scientific literacy, or different approaches to constructivistic learning. A promising starting point might be an initial reflection upon one's *a priori* beliefs about teaching and learning. A self-reflection session focusing on the question of teacher- or student-centeredness often helps to plant the seeds of change. As suggested in Markic and Eilks (2008), tools like DASTT-C (or its modified version) can readily and easily applied for this purpose.

[4]PhD Student at Middle East Technical University

Abstract: The purpose of this study was to investigate pre-service chemistry teachers' understandings and misconceptions regarding the electrolytic cells in electrochemistry. The sample of this study was composed of 31 pre-service chemistry teachers in chemistry teacher education program in Turkey. Data was collected via seven open-ended questions related with electrolytic cells. Two researchers analyzed written responses of participants independently, then came together and discussed the answers to reach consensus. Results revealed that pre-service chemistry teachers had difficulty in understanding of electrolysis and most of them could not distinguish electrolytic cells from galvanic cell. Also, they could not identify the electrodes as anode and cathode in electrolytic cells, so they could not predict the product of the electrolysis correctly. It can be concluded from the results of this study, pre-service chemistry teachers had misunderstanding regarding both galvanic and electrolytic cells. Misconceptions and conceptions of pre-service chemistry teachers should be detected and remedied in this topic in teacher education programs so they can educate their students effectively regarding electrochemistry topic in future.

Keywords: pre-service chemistry teachers, electrochemistry, electrolytic cells, misconceptions, teacher education

BACKGROUND, FRAMEWORK, RATIONALE, AND PURPOSE

Electrochemistry has been regarded as one of the most difficult chemistry topics in which both pre-service teachers and students have learning difficulties (Nakhleh, 1992; Ogude & Bradley, 1994; Sanger & Greenbowe, 1997a). A number of researchers investigated students' and teachers' misconceptions in electrochemistry topic (Doymus, Karacop & Simsek, 2010; Garnett & Treagust, 1992a, 1992b; Ogude & Bradley, 1994; Özkaya, 2002; Sanger & Greenbowe, 1997a, 1997b). Garnett and Treagust (1992b) investigated high school students' understanding of electrochemistry in terms of electrochemical and electrolytic cells and identified students' misconceptions in these topics and possible sources of these misconceptions. In 1997, Sanger and Greenbowe replicated the study of Garnett and Treagust (1992b) with college chemistry students and found similar findings with them as students had learning difficulties and misconceptions in galvanic, electrolytic and concentration cells. Moreover, Sanger and Greenbowe (1997a) emphasized that identifying misconceptions was important to help learners understand this topic meaningfully. Although there have been studies on conceptions of students about electrochemistry topic at high school level, studies conducted with pre-service teachers are few (Ogude & Bradley, 1994; Özkaya 2002).

Therefore, this study investigated pre-service chemistry teachers' understandings and misconceptions regarding the electrolytic cells in electrochemistry. The research question of this study is presented below:

What are the conceptions of pre-service chemistry teachers regarding electrolytic cells in electrochemistry?

METHODS

The sample of this study was composed of 31 pre-service chemistry teachers (PCT) in chemistry teacher education program in a state university in Turkey. Data was collected via open-ended questions. Seven open-ended questions were designed by researchers in the light of related literature (Garnett & Treagust, 1992b; Sanger & Greenbowe, 1997a). Suggestions of four experts in chemistry education were taken into consideration while developing the questions. Each participant was asked the following open-ended questions:

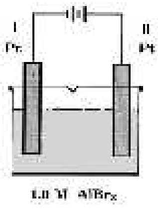

Figure 1

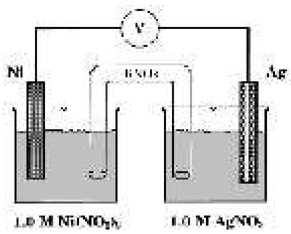

Figure 2

"Please answer these questions considering the electrolytic cell given in Figure1.

1. How does Figure 1 differ from Figure 2? Explain.
2. How would you determine which electrode is the anode and which is the cathode?
3. In which direction do the charges flow in this cell to complete the circuit?
4. What reactions are taking place at each electrode?
5. Compare the mass of electrodes before and after the reaction. Please explain your answer.
6. Can you predict the E value for this set-up?
7. Suppose the solution was changed to molten $AlBr_3$, would you expect happen any differences? Explain your ideas."

Qualitative content analysis (Creswell, 2009) was used in order to analyze the data. Firstly, two researchers analyzed written responses of PCT independently, then came together and discussed the answers to reach consensus.

RESULTS

Results of the study indicated that half of the participants gave irrelevant responses to the question asking the difference between galvanic and electrolytic cells. They stressed the differences such as electrolytic cell has no salt bridge, it has one type of solution, and the electrodes are the same. On the other hand, participants who responded the question correctly claimed that in galvanic cells the reactions are spontaneous while in electrolytic cells they are nonspontaneous.

Only six out of 31 participants were successful to determine the anode and cathode of the electrolytic cell by using the polarity of the battery. On the other hand, sixteen wrote incorrect responses. Three of them used standard reduction potentials to identify anode and cathode. For instance, one participant wrote "*I will determine anode and cathode by using standard electrode potential. The substance which has the higher potential will reduce; the other one will be oxidized.*" Five participants who gave incorrect responses to this question claimed that the reactions occurring at electrodes will identify whether the electrode is anode or cathode. For instance, one participant wrote that "*The electrode in which oxidation reaction occurs is anode, the other one is cathode.*" In addition, one of the participants who responded this question incorrectly claimed that as the electrodes were in the same beaker and made from the same metal, so any of the electrodes may be anode or cathode. For instance, one of the participants explained this situation as "*both of the electrodes are made up of platinum so either of them can be anode or cathode*." The rest of the participants' responses were evaluated as trivia or no answer. These results indicated that most of the PCT did not know the function of the battery used in electrolytic cells in terms of determining anode and cathode.

Ten out of 31 participants could correctly state the direction of electron flow. Other participants either did not state the direction of electron flow or state that it would be from anode to cathode although they could not identify where the anode and cathode were. Moreover, considering the flow of other charges, six participants stated that cations would go to cathode while anions would go to anode and did not consider that water could be oxidized or reduced.

None of the PCT could correctly predict both $H_{2(g)}$ and $Br_{2(g)}$ as the products of electrolysis. One of them stated that H_2O would reduce at cathode, however could not predict the product correctly. While six of them stated that $Br_{2(g)}$ would occur at anode, $Al_{(s)}$ would occur at cathode instead of $H_{2(g)}$. This result suggested that PCT ignored the reduction of H_2O and thought that the cation (Al^{+3}) in the solution would reduce. This point of view led these PCT to think that while the mass of cathode would increase due to precipitation of aluminum at cathode, the mass of anode would not change due to the formation of $Br_{2(g)}$. Also, four PCT stated that while the mass of cathode increases, the mass of anode decreases likewise it generally occurs in galvanic cells. This result indicated that these PCT had incorrect idea regarding Platinum metal as reactive. The rest of PCT could not respond the question related with the changes in mass of electrodes.

The question related with E value for electrolytic cell was correctly responded by only six PCT as $E < 0$. Five of PCT responded this question incorrectly as $E>0$. These participants were not aware of the fact that in electrolytic cells nonspontaneous reactions occur. The rest of the participants did not respond the question.

The last question was correctly responded by only one participant as the product of electrolysis of $AlBr_{3(l)}$ would be $Al_{(s)}$ and $Br_{2(g)}$. While six participants could not respond this question others gave incorrect responses to it. For instance; some of them claimed that as $AlBr_{3(l)}$ was not formed of ions it could not be electrolyzed. Also some participants claimed that as the concentration of $AlBr_{3(l)}$ was greater than $AlBr_{3(aq)}$ reduction reaction would occur more easily.

CONCLUSIONS AND IMPLICATIONS

The results indicated that PCT had difficulty in understanding of electrolysis and they have incorrect knowledge regarding this topic. The misconceptions concerning electrolysis detected in this study were consistent with students' misconceptions presented in previous studies in the literature (Garnett & Treagust, 1992b; Sanger & Greenbowe, 1997a). Most of the PCT could not distinguish electrolytic cells from galvanic cell and this led PCT to have misconceptions such as they thought electrodes would react even they were made up of platinum or the battery has no effect on the site of the anode and cathode. Furthermore, due to not identifying the electrodes as anode and cathode, they could not predict the product of the electrolysis correctly. It can be concluded from the results of this study, PCT had misunderstanding regarding both galvanic and electrolytic cells. In the light of the findings, this study has some implications. Misconceptions and conceptions of PCT should be detected and remedied in this topic in teacher education programs. To clarify, distinction between galvanic and electrolytic cells should be discussed as well as discussions about important concepts in electrolytic cells can be beneficial for prospective teachers to be aware of their conceptions. It is important to graduate prospective teachers with sound understanding of electrochemistry topic like other chemistry topics. Hence, they can educate their students effectively regarding electrochemistry topic in future.

THE USAGE OF VISUALIZATION IN CHEMISTRY TEACHING AND PRE-SERVICE EDUCATION: SOME FINDINGS

Celeste Ferreira[1] *and Agnaldo Arroio*[1]
[1]Faculty of Education, University of São Paulo, São Paulo, Brazil

Abstract: This study is a qualitative research where we try to find out and analyze the conceptions of pre-service teachers (n=24) of a Chemistry class from University of São Paulo (USP), São Paulo, Brazil, about the usage of visualizations in chemistry education. In order to reach our aims in the beginning a questionnaire was applied to all the class and at the end of the semester two groups of seven pre-service teachers were chosen to apply a semi-structured interview that focused their own choices and the use of visualizations as teachers in a mini-course that they presented to middle school pupils at São Paulo University. The speeches analysis (questionnaire, interviews and mini-course reports) was done based on the Michel Foucault's contribution to speech analysis. As a result of this study we highlight that the theoretical conceptions of these pre-service teachers are superficial, not solid, and sometimes even become misconceptions. The speech of these pre-service teachers on visualizations presents as main referent the abstract nature of chemical concepts and the capacity that this resource has to make chemistry classes more interesting, to keep students attention and to make chemistry concepts close to quotidian. We also found in these statements the presence of their college, the practices of their own teachers and the IT industries. The choices on visualizations and the way that they used these tools were strongly related with the presented referents, specially with their capacity to keep attention, to increase the class interest, or the capacity to make chemical concepts more close to the reality and/or quotidian.

Keywords: chemistry teaching, pre-service teacher's education, visualization

INTRODUCTION

Models and the role of visualization in science and science education, especially in chemistry, have grown up during the last decade. Chemistry involves the interpretation of matter observables changes (e. g. color changes or gas release) on the macroscopic level in terms of imperceptive changes on the submicroscopic level. These changes are represented in a symbolic and abstract way using symbols, equations, graphics, etc. With the purpose of making these representations accessible to the students, teachers are using visualizations more frequently. The accelerated development of information and communication technologies followed by several studies in the cognitive theory area, have promoted the construction of many visual tools (3D concrete models, virtual 2D and 3D images, simulations, animations, interactive software, etc.) that have been placed to the disposition of educators. With the frequent use of these tools, images became the main vehicle of information, and if the learning impact is bigger so is the risk of misconceptions if the choice of the image is inappropriate. Progressively educators began to recognize the value of the visual component on the chemical knowledge, which was until then, only attributed to the verbal and mathematical language; nevertheless the pictorial chemistry language is by itself a higher structured language (Ege, 1994). With Jonhstone (1991) the chemical knowledge was divided in three levels of representation (submicroscopic, macroscopic and symbolic). For a student immersed in the macroscopic world, the reality, it becomes very difficult for him to

understand the concepts and the processes located at the submicroscopic level and represented in the symbolic language of chemistry. There is a stead growing body of research that suggests that the use of visual tools helps students' transition between these levels of representation.
Reviewing the literature we found that there are three common academic usages of visualization in psychology and educational research (Gobert, 2007): external visualization, internal visualization and visualization as a type of spatial skill. In a simple way we can say that external visualizations in science refer to graphics, diagrams, models, simulations, etc, representations typically used in learning; internal visualizations are used to describe internal mental constructs, i.e., mental models; and visualization is also used to describe a type of spatial skill, the ability to manipulate or transform the image or spatial patterns into other arrangements. Also, according to Gilbert et al. (2008) a central topic that often crosses these studies is the definition of the term "visualization". There are two conventions, in convention 1, visualization is a verb (to visualize something is to mentally act on it), in convention 2 visualization is a noun (visualization is something in the public realm). Inevitably, there are also studies that cross the two conventions, for instance, studies about "visuospatial thinking".
We found literature approaching this issue in the sense of convention 1 that dealt with questions such as: How is a visual representation turned into knowledge? What are the mental processes involved in attaching a meaning to a representation? What mental and brain processes are involved in "seeing"? (Reiner, 2008). Other authors (Gilbert, 2007; Rapp & Kurby, 2008; Briggs & Bodner, 2007) also present their ideas about these concerns. Gilbert refers the importance of developing "metavisual capability" or "metavisualization", the acquisition of fluency in visualization and the making of meaning for any representation (Gilbert, 2008). This author suggests that this development could be done by general good practice in the use of representations by teachers and in textbooks and by the specific cultivation of the skills involved (Gilbert, 2007). For Gilbert the skills involved are: being able to move fluently between two-dimensional and three-dimensional representations of a given model (translate); being able to mentally change the perspective from which a given three-dimensional representation is viewed (rotation); being able to operate on the representation itself, particularly in terms of taking mirror images of it (reflection and inversion).
Like we mentioned before, there is another trend of research that uses the term visualization in the sense of convention 2, a noun, something that has been placed in the public realm in either a material object, visual, verbal or symbolic form. Here we found several studies (Wu, Krajcik & Soloway, 2001; Ferk et al., 2003; Santos & Greca, 2005; Tasker & Dalton, 2006; Kozma & Russell, 2007; Arroio & Honório, 2008) that by using a different approach try to evaluate the use of different kinds of visualizations in chemical instruction. Most parts of these studies are only quantitative and through a series of specific tests they try to evaluate the pupil's apprenticeship and indirectly the effectiveness of the visualization used.
In a literature review on this area we found some recent studies (Justi & Gilbert, 2003; Justi & Driel, 2005) that investigate the teacher's views/knowledge on the nature of models and modelling that point out the need to work these concepts in pre-service and in-service education. In their research they found teachers with less than satisfactory understanding of the nature of "model" which has implications on their teaching approaches on this concept.
With the development of this investigation we try to identify and analyze the conceptions of pre-service teachers (n=24) of a Chemistry class from University of São Paulo (USP), São Paulo, Brazil, about the use of visualizations in chemistry education. The data analysis was done based on Michel Foucault (2000) contributions about speech on educational field. Foucault analyzes the discursive and practical conditions for the existence of truth and meaning. The statements are 'events', because, like other rules, they appear at some time.

Statements depend on the conditions in which they emerge and exist within a field of speech; the meaning of a statement is reliant on the succession of statements that precede and follow it. So, as a historical method, the analysis of the statements is done in a historical context: the discursive formation. This author also attributes a mutual conditioning between the speeches practices and the none-speeches practices, which we consider very relevant on this work. As we are going to see the way they use these tools is strongly related with the conceptions they have on models and visualization.

METHODOLOGY OF RESEARCH

We used a qualitative research in our study, applying a questionnaire and a semi-structured interview to a class of 24 graduates of a chemistry education course of São Paulo University (USP), Brazil. These pre-service teachers (undergraduate) had a range of academic backgrounds, but the most important is that 8 of them had no experience in teaching, but the other 16 had already some teaching experience. We applied a questionnaire with 17 open-ended questions seeking to know what conceptions about visualization, use of models and images they possess, and at the same time what was the contribution of their graduation on this issue. We also want to know if they felt that they are prepared to teach in this new teaching environment. During the Chemistry Teaching Methodology II class, these pupils had to prepare a mini-course to offer to middle school pupils. This mini-course takes two days, and these graduates are responsible for the entire mini-course (subjects, methodology, assessments). At the end of this mini-course we applied an interview on two groups of seven graduates with several questions. The first set of questions (nine questions, common in both interviews) were more general and aimed to know what conceptions they had on visualization and it's use, the next questions (three for the first group and four for the second group) were about their own choices on the visualizations used in their mini-course classes. We also analyzed their mini-course reports.

The speeches analysis of their statements was done, as mentioned before, with Michael Foucault's contributions. According to this author each statement can be characterized by four basic elements: a referent, a reference to something that we identify, the person, someone that assert something (in the sense "of position" to be occupied), an associated field (the statement doesn't exist isolated, but always associated to other statements, from the same speech or from other speeches), and finally a specific materiality, the concrete forms where he appears (oral speech, write speech, tapped things that can be reproduce through practices and social relationships) (Fischer, 2001).

RESULTS OF RESEARCH

According to the chosen theoretical framing, the speech of these pre-service teachers on visualizations presents as main referents: the abstract nature of chemistry concepts, the capacity that this resource has to make chemistry classes more interesting, "*to break the monotony"* or to keep students attention, and to make chemistry concepts close to quotidian. Only a few made some references to their educational value, and these references were found mostly in the questionnaire, on practice they used them specially in order to get and keep student's attention and to discuss prior knowledge. We also found on their statements references between these tools and the realism that they confer to the objects of the submicroscopic chemical dimension. This was very clear, for instance, when they introduced an animation in the class "*Let's see what happens when we put salt on water*."

Pursuing our speech analysis we must characterize the person. Who speaks? What is the status of these students? Where they got this speech? Where they put into practice? The person of these speeches is a student from a university, considered the best of South America, who already takes a position as a teacher (majority) in the Brazilian school. He is a last year graduate from the chemistry education course, whose curriculum presents a division between pedagogical subjects and specific-contents subjects, so the discussion of the theoretical issues related to the use of these tools isn't yet effective. The recurrent use of these tools requires a good practical knowledge (technical knowledge) interconnected with a theoretical background in order to allow teachers to find adequate pedagogical solutions to its use. When they were asked to explain their choices of visualizations they show a weak theoretical knowledge about this issue, they expected as they said, "*the images made their role*", and if everybody uses them, so they must be important for learning. So, the person of this speech is mainly a teacher who the society began to make available a set of visual tools and demand its use in a classroom without the necessary education. So, in practice we have a teacher who makes a none-reflected use of these visual tools, where image is a source of entertainment; these conceptions arise in an imagetic culture. The influence of the media grasps all the social classes and institutions, among those, school, and especially chemistry teaching. They get this speech mainly in the school through the speeches and practices of their own teachers about the use of visualization, on the papers and books about this issue, and on the governmental policies in the education field that encourage and promote the use of these visual tools. That's also in their university that this speech appears, talking with their teachers and their colleagues, on their practices, reports, tests, etc. They also spread this speech as teachers on their schools.

Featuring the associated fields that appears in the statements of this future graduates in chemistry teaching about visualization's use, we found a set of statements deriving, for instance, from pedagogy: "*To arouse student's interest, keeping them concentrate in classroom allowing him to develop abilities and perceptions about the macro and submicroscopic world of chemistry*." Or from didactics, the use of these tools appears related with the need to convert the chemical concepts in school contents. We can see on their statements the presence of the IT industries (none-speech domains), "*We have a salt dissolution, we must use an animation, it has to be, something dynamic, it has to be…*". Nevertheless, as we said before, we found a great number of references from the media field, such as "*The idea was to impact the audience*.", "*The color keeps the attention*". In order to finish the analysis of this speech, we must characterize the materiality of these statements. These statements appear on the written answers to a questionnaire, on the assessments reports of the mini-course and on the interviews that they gave to this research. This status indicate that they are data for a research and they are going to be a part of the literature about this subject, they are going to circulate in the academic field, they will be decomposed, manipulated and eventually destroyed.

DISCUSSION

The result obtained in this sample is coherent with several studies (Gilbert, 2007; Ferk et al., 2003) that emphasized that the ready availability of powerful computers made this visualization tools very popular, and now it is very difficult to find novice students, expert students or even teachers in exercise that have never had any contact with these tools.

Searching the speech regularities we found as we mentioned before, several statements that relate the use of visualizations with the abstract nature of some identities and processes of the chemistry world. This concern with the understanding of the submicroscopic world appears in chemistry on the last decades of the past century. Several researchers attribute to the great difficulty that students have to cross the three levels of chemistry (macrochemistry, submicrochemistry and representational chemistry (Jonhstone, 1991) a major cause for the school unsuccessful in this science. These issues are discussed on the pre-service education in some of the pedagogical subjects, emerging in the speech of these pre-service teachers about the use of visualizations. Simultaneously the society expects that schools increase the success taxes and introduce new methodologies and new learning tools. These are some emergency conditions and the relations that incite the use of these visual tools, and the appearance of some none-speech practices.

The lower number of references between visualizations and its role in building knowledge is according Foucault' theory tied to the power and knowledge dynamics of our time. In one end this "event" shows the lack of education on this issue and on the other end the strong influence of the image in ours lives. As we can see in our results we found several statements relating visualization with the possibility to get students attention, to make classes more interesting, and in practice this was the most frequent purpose for the use of these tools. They don't show any especial understanding on how a visual representation is turned into knowledge and what are the mental processes that are involved in attaching meaning to a representation. They never mentioned the skills involved (Gilbert, 2007) in learning through these visual tools and the need to previously discuss with the students the codes and conventions associated to any visualization. They completely forgot that the intended purpose of the visualization and its relation to the referent is obvious for the teacher but sometimes is opaque to the novice pupils (Uttal & Doherty, 2008).

Describing this *Teacher*, according to Foucault's theory we found a person very conditioned by his pre-service course and by the changes on his society, especially in education. The way they use these tools doesn't reveal a reflexive practice, mostly they merely used these tools with no reflection on the impact of these tools on the apprenticeship. This concern with the need to become a reflexive teacher (Schön, 1992) is related with the possibility of him questioning, understanding and if necessary change his practice.

As a consequence, this reflects on the associated fields that appeared on their speech about the use of visualization on chemistry education. On their speech about these tools, as we referred before, we found a larger number of statements from the media field, especially related with the images impact, followed by a much lower number of statements from the educational field (pedagogic and didactic). This influence sometimes goes against to the initial use of representations on chemistry that was limited to communication and heuristics creation with the purpose to preview proprieties of the chemical objects, assigning to these tools ways of use very distinctive from that ones historically conceived in the middle of the XIX century. One of the great problems of using these tools without the necessary education stands on the fact that sometimes its usage is to give existence to objects that exists only in theory. Here we can see the need to teachers had a good comprehension to the concept of model in chemistry and the role of visualizations in chemistry education.

CONCLUSIONS

As conclusion we can say that these pre-service teachers aren't yet sensible to the impact of visualizations and they don't know how to use them in a fruitful way. It's clear on their answers that their use of visualization is more concerned with the external effect that visualizations cause, than to the internal effects of visualization itself. They never mentioned the supposed role of (external) visualizations on internal visualizations (mental models) and it seems that they aren't really aware of visualizations *power*. We could say that they use visualizations in a *naive* form. This was very clear when they used the animation; first they never mentioned its use as a representation and second they don't discuss with pupils the codes and conventions associated to every visualization. We also can say that there is an absence of some knowledge related to the skills need to make any visualization meaningful. First they don't show any particular understanding that it is necessary to improve *metavisual competence* (Gilbert, 2007) on the pupils, and second it seems that some of them begin to believe that visualizations could be a panacea for teaching some difficult scientific topics. Based on Michel Foucault (2000) we can refer that their choices on visualizations are strongly related to their conceptions about this issue and their conceptions about it are very week, demonstrating several gaps in their theoretical knowledge on models and in the role of visualization in chemistry education. The set of referents founded reveal a great influence of the media in their practices with these tools, which is a product of our historical context. As a final take away we can say through this sample that is necessary to improve the training of our future teachers and supply them with all the theoretical background necessary for them to apply this new tools with effectiveness in chemistry teaching.

THE PRINCIPLES OF A SHORT TIME SEMINAR FOR DEVELOPING PROSPECTIVE GREEK PHYSICS TEACHERS' PCK

Vassilis Grigoriou[1] and George Kalkanis[1]
[1]Science, Technology and Environment Laboratory, Pedagogical Department P.E., University of Athens

Abstract: This study is a part of a wider effort to propose a curriculum and afterwards a time table for a short time didactical seminar which aims at prospective Science teachers and would affiliate issues of educational methodology and educational exploitation of technology. In this paper are described the educational actions that took place in order to develop the Pedagogical Content of Knowledge (PCK) of twelve students of the Physics department of the University of Athens through a thirty hours seminar. The seminar involved basic didactic concepts, educational methodology matters and ways to use educational technology. During the whole project students designed and they also developed educational material and at the end they conducted a normative lesson. The first findings show that they had formed only a very primitive PCK at themes that involve students' attitude, use of experiments as an educational tool, self-evaluation and decision rationalization. On the other hand they have developed their PCK at fields that don't include such delicate issues and that can be described through general norms, such as adopting an educational methodology, performing experiments, producing educational material and using technology. Further effort should me focus on prospective students' attitude towards technology implementation, students' learning and educational decision rationalization.

Keywords: PCK, prospective Greek teachers, seminar

INTRODUCTION-BACKGROUND

During the last years there has been a large conversation in Greece concerning the instructional quality and the educational results at the field of Science. Data interpretation of the PISA draw rather disappointing conclusions for the educational system as a whole and therefore education communities have been striving for increasing the quality of science and technology education. The Greek ministry of Education has recently proclaimed a wide program in order to change the curriculum in the primary and secondary education, mentioning the key role that teachers should play in this effort for the new era in education. It is clearly articulated that "teachers should be able to produce their own educational material that will reflect their own viewpoint and values about science syllabus". Moreover it is acknowledged the necessity to support teachers in their professional growth through a procedure that will affiliate contents that pertaining to educational methodology and educational technology, helping them to introduce the new acquisitions into their daily teaching.

Previous research efforts (Grigoriou & Kalkanis, 2009, Grigoriou et al, 2010, Grigoriou, Vithopoulou & Kalkanis, 2010) imply that Greek prospective Science teachers form only a very primitive PCK regarding the characteristics of some aspects, such as representations of subject matter, didactical strategies, the purposes and goals for teaching science, objectives and specific curricular programs and materials, students' attitude and requirements for learning specific science concepts self-evaluation and decision rationalization. On the other hand they have developed their knowledge at fields that don't include such delicate issues and that can be described through general norms, such as adopting an educational methodology, performing experiments, producing educational material and using technology.

In parallel, studies that have been conducted in Greece (Kariotoglou, 2002) show that the knowledge that Greek University students obtain from their studies is insufficient for their professional development and therefore is necessary to provide them an appropriate support in terms of pedagogical content. This is where PCK arises as one of the most crucial sub-domains (e.g. Grossman, 1990; Shulman, 1987) of teachers' professional knowledge. It should be mentioned that PCK is not a widely spread notion at the Greek Universities, as it hardly appears at the syllabus of the faculties' or departments' curriculum, apart from some prominent exceptions (such as University of Florina). Research pursues more or less the same direction as at the last Greek conference that took place at the mid of April of 2011, there were announced only 2 presentations regarding PCK.

A number of studies imply that educational support and appropriate opportunities to student teachers to design, implement and reflect on their educational action may contribute to broaden their PCK. Clermont, Krajcik, and Borko (1993) found that the PCK of preservice science teachers participating in a short, intensive workshop on specific teaching strategies developed towards that of expert teachers. Van Driel, De Jong and Verloop (2002) suggest that specific courses or workshops during teacher education have the potential to affect PCK, for instance, by extending preservice teachers' knowledge of students' preconceptions or their knowledge of specific representations of subject matter. On the other hand, according to Tytler (2005), training programs concentrated in a short single period are ineffective in promoting changes in teaching practice: training needs to last a long time and to be inserted into a real school context to embed new ideas into a teacher's personal experience. Alike, Adams and Krockover (1997) found that workshops can have a negative effect because they can stimulate preservice teachers to copy conventional instructional strategies, stressing procedures rather than student understanding.

PURPOSE-RATIONAL

Trying to contribute to the discussion according to whether PCK can be considered as a frame to design and implement seminars for prospective science teachers' professional development, this study describes the first steps of a wider effort to propose a curriculum and afterwards a time table for a short time didactical seminar in order to develop prospective Physics teachers' PCK, mentioning the experience that has been earned from this first attempt.

Many studies have been conducted in order to evaluate the effectiveness of this approach, targeting at researchers' contemplation not only at PCK theory but also at the means that PCK should be managed, promoting this thesis (Niess et al., 1999, Zembal – Saul et al., 1999, Watters et al., 2000, Van Driel et al., 2002, Aaltonen et al., 2003).

More precisely the research questions were:

1. How, and to what extent, the preservice physics teachers develop concrete aspects of PCK (knowledge of representations of subject matter and

understanding of specific learning difficulties and student conceptions) by participating in this short time seminar?
2. What are the participants' perceptions concerning the role of this seminar, in helping knowledge base development (actions, syllabus, tutor)?

At this point it should be clarified the framework within we use the term of PCK. After the initial intromission of the concept of PCK from Shulman in 1987 as "a special amalgam of content and pedagogy that is uniquely the province of teachers, their own special form of professional understanding" a lot of proposals have been made as didactical strategies that can materialize this basic concept. Although there has been no consensus on the PCK models and components, all scholars agree on Shulman's two key elements - that is, knowledge of representations of subject matter and understanding of specific learning difficulties and students' conceptions (Van Driel, Ver loop & de Vos, 1998).

An auxiliary verbalization for a science teacher are the answers to following questions: What shall I do with my students to help them understand this science concept? What materials are there to help me? What are my students likely to already know and what will be difficult for them? How shall I best evaluate what my students have learned?" Answers of these questions are the fundamentals of pedagogical content knowledge (Magnusson, S. Krajcik, J., & Borko, H., 1999).

RESEARCH FRAMEWORK-METHODS

The sample

The participants where 12 graduands of the Physics Department, who had attended a course of general didactic comprising principles of teaching, instructional strategies and use of technology in developing educational material. All the students were voluntary offered to participate and expressed their will to follow science teacher carrier. The tutor was the first author of the article.

Seminar Description

The seminar took place at the Science, Technology and Environment Laboratory of Athens Pedagogical Department. It lasted 15 sessions, 2 hours each, and we implemented it 5 times during the last 4 years. At each seminar participated 2 or 3 students. Viz, were tarined 3 dyads and 2 triads of students. That indicates the differentiation of the sample at each seminar.

Each session lasted 2 hours and it was divided in three terms: At the first term it took place an introduction from the tutor to the notion of PCK, analyzing each time different aspects. A presentation of normative educational material followed, affiliating the proposed concepts. At the second term tutor proposed a concrete science principal (such as electricity from the view of microcosm) and afterwards students were developing their lesson plans and the appropriate educational material for the specific subject matter issue. At the third term a procedure of reflection upon the developed material was taking place and at the last sessions a reflection upon the microteaching that students had already conducted.

Research tools

To capture a highly complex construct such as PCK in this qualitative research, a multi-method evaluation was followed. The tools were notes taken by the tutor in each session (during the second and third term), semi conducted interviews of the participants at the beginning and at the end of the seminar (audiotaped and then verbatim transcripted), the portfolio of students' developed material (lesson plans, worksheets, apparatuses), the videotaped microteaching that each student conducted.

The interviews at the beginning of the year focused on the students' educational background, expectations as a prospective science teacher and expectations from the seminar. Interviews with the students at the end of the seminar focused on experiences during the seminar, reflections on the assistance that was provided and proposals for future enhancement. Knowledge of representations of subject matter and understanding of specific learning difficulties and student conceptions were delineated through tutors' notes that were taken at the second term and through portfolios' analysis, identifying the educational reasoning at students' choices. Analogous processes to capture aspects of PCK were adopted by numerous scholars, such as "Lesson Preparation Method" by de Jong (2000), "CoRes and PaP-eR" by Mulhall, Berry and Loughran (2003), lesson preparation method followed by interview (Van der Valk & Broekman, 1999).

At the 13th approximately session of the seminar, student teachers conducted a microteaching. The subject topic was mutually agreed between the tutor and each of the student teacher. This lesson lasted 45min and it was conducted to freshmen students of the Pedagogical department. The reason for this choice was twofold: firstly convenience in terms of scheduling and handling and secondly because they present similarities with school students in terms of misconceptions and attitude towards science learning. Each microteaching was videotaped and used for reflection at the third term of the rest sessions.

The semi structured interviews were transcripted and analyzed by student's name and by category (e.g. expectations from the seminar, experiences during the seminar, reflections on the assistance that was provided, proposals for future enhancement). The analysis was mutually agreed between 2 independent judges.

The portfolio and tutor's notes was analyzed by student's name and by knowledge base category, generating subcategories for more specific tincture, such as didactic strategies, students' misconceptions, curricular material.

RESULTS-CONCLUSIONS

Knowledge of representations of subject matter

At the beginning of the seminar, all of them expressed negative attitudes toward the need to follow an educational methodology which is based to inquiry, because it requires more demanding preparation and thinking skills comparing to learning by lecture, with which they were familiar. However, when they understood more about the inquiry model of instruction and got involved to use it through their lesson plans they gradually developed more positive attitudes toward inquiry activities. The lesson plans' preparation enhanced the participants' understanding and reasoning about their choices and prompted complex thinking about physics teaching and learning. However, they face difficulties in tailoring activities and materials to the needs of their students and monitoring students' learning. At microteaching activity student teachers got involved with teaching in a conserved context. They had their first experience from the point of view of class management, time management and the complex nature of educational decision making. However, it was clearly revealed their weakness on content knowledge.

Understanding of specific learning difficulties and student conceptions

The participants came to the course with a varied mixture of existing knowledge and experiences concerning teaching and learning. Although the participants had attended a relative course all of them knew little about teaching, learning, and assessment. During the activities of their lesson preparation they emphasized the importance of being aware of students' misconceptions before teaching a topic although they didn't achieved a deeper level of dealing with them even at this preliminary stage of their lesson preparation. They became anxious in developing their lesson plans so they omitted anything that they regarded it was difficult for them to manage with, besides the recognition to the importance that may have that choice to the efficacy of their lesson. At microteaching activity student teachers faced questions that revealed misconceptions from the side of the students. Unfortunately student teachers they were not able to handle them choosing the convenient for them way to ignore and to change the discussion (Halim and Meerah, 2002).

By microteaching activity student teachers seemed to shift their awareness about teacher's role to a level that recognizes the importance for students learning to get engaged and facilitated into it rather than participating in an knowledge transmition procedure. Also, during the periods of lesson planning and micro-teaching, student teachers gained direct experience also as a learner and as a teacher. Reflections on that procedure led to the acquisition of a broaden knowledge encouraging the participants to develop and implement their topicspecific PCK, something that is also mentioned by Cochran et al., (1993).

Participants' perceptions concerning the role of this seminar, in helping knowledge base development (actions, syllabus, tutor)

Teachers felt personal interest because of their direct involvement in procedures of planning and implement a lesson which led them to a deeper understanding of the topic. Also this acted as a springboard to personal engagement to change traditional presentations by introducing the new acquisitions into their teaching.

IMPLICATIONS

Since the majority of the student teachers endorsed technology's worthiness in science education we suggest that technology should be studied further along the procedure of a seminar that it has the ambition to expand student teachers' PCK. A better established framework for the role of technology in teachers' education should be followed in the forward approach of the seminar, where TPCK could act (or not) supplementary.

Also, improvements should be made at the syllabus and the educational material provided towards technology implementation in science education and misconceptions manipulation as already mentioned before. Sudents teachers' inefficacy to handle students misconceptions could be the incorporation of more palpable proofs for the role that students' attitude and misconception play in their learning, through alterations to the seminars' syllabus so that it can comprises sessions with videotaped normative lessons and more chances for real condition teaching. This selection could provide useful service and in other aspects of PCK such as learning teaching strategies, setting and accomplishing specific educational goals as mentioned by Abell and Cennamo, (2003).

In parallel, an appropriate software development and implementation may contribute to facilitate student teachers to incorporate technology into their lessons, extricating more time for more fruitful actions towards the direction of students understanding.

IDENTIFYING ELEMENTS OF PCK IN CHEMISTRY TEACHER EDUCATION

Nicola Großebrahm[1] *and Stefan Rumann*[1]
University of Duisburg-Essen, Germany, Faculty Chemistry Education

Abstract: The explication of the pedagogical content knowledge (PCK) construct often remains subject-unspecific. Additionally the elements of PCK that can be acquired at university, where prospective teachers usually only have few opportunities to practice teaching, have not yet been clarified. This study aims to identify elements of chemistry-specific pedagogical content knowledge that are related to university teacher education programs. To elucidate the elements that are relevant in teacher education, expert-interviews with teacher trainers were conducted. By means of content analysis, the method of *analytical hierarchy*, based on Spencer, Ritchie & O'Connor (2003), is suitable for (1) developing categories, (2) labeling the interview data, and (3) abstracting from individual viewpoints to aggregate the statements of different experts to themes and concepts of chemistry-specific PCK for teacher education programs. The process of analysis is illustrated with an example that refers to the general facet: *knowledge of curricula and objectives*. Teacher trainees have to be familiar with the spiraling character and the chronology of chemistry issues. They should be sensitive to learning difficulties that may emerge from this and should have methods at their disposal for handling them.

Keywords: teacher education, chemistry-specific PCK, expert-interviews, content analysis, professionalization

Introduction

Since Shulman (1986, 1987) proposed a typology of teachers' professional knowledge, this approach has been pursued by numerous researchers. The core constructs content knowledge (CK), pedagogical knowledge (PK) and pedagogical content knowledge (PCK) have built the foundation for different studies. PCK attracts a particular amount of attention because it represents genuine teacher-specific knowledge and skills. Although more or less similar conceptualizations have been made, there are still no subject-specific (e.g. chemistry-specific) descriptions of PCK yet (Kind, 2009). Existing approaches often focus on pre-service (e.g. Van Driel, Beijaard & Verloop, 2001) and in-service teachers (e.g. Mulhall, Berry & Loughran, 2003). This is due to the common assumption, that teachers' competences develop through action and experience in class. In terms of university teacher education and its impact on the development of professional competence as well as the character and content of adequate professionalization, further research is still needed (Borko, 2004; Blömeke, Felbrich, Müller, Kaiser & Lehmann, 2008; Krauss et al., 2008).

With regard to the German teacher training program and its structure, it is necessary to draw a distinction between different levels of PCK. German teacher education consists of two phases. The first phase takes place at university. It emphasizes on acquiring theoretical knowledge in three areas: the subject-related scientific discipline, educational science and subject-related didactics. Student teachers have to pass a first state examination (or nowadays a bachelor and master exam) before they start their preparatory-service at school, which is the second phase. Pre-service teachers finish this supervised practicum in the field with a second state examination. The study aims to identify elements of chemistry-specific pedagogical content knowledge that are related to university teacher education programs.

We refer to a sociological approach in order to characterize the knowledge that is imparted at university. According to Radtke & Webers (1998), knowledge that is acquired at university has to be seen as the basis for professionalization. They distinguish between three types of knowledge: reflective knowledge, decisional knowledge, and routines. Decisional knowledge and routines are accumulated through teaching practice. At university, mainly reflective knowledge is acquired, for which teaching experience is not a necessary condition. By contrast, theoretical knowledge should not be communicated without drawing connections to practical examples. Teacher educators should link the reflection of theories to practical situations in order to prevent knowledge from idling (Eraut, 1994).

Radtke & Webers characterize this knowledge as a theoretical frame that should enable pre- and in-service teachers to reflect and justify their classroom-activities. For teachers these abilities are essential (Darling-Hammond, 2006). Eraut (1994, p. 60) describes the application of theories in order to "[…] interpret, explain or judge intentions, actions and experiences […]" with the term *theorize*. Non-professionals who are not able to *theorize* often analyze classroom activities according to their own experience as pupils. It is an essential goal of university teacher education to avoid that. The typology of knowledge of Radtke & Webers is not related to a specific content and is therefore applicable to every facet of (prospective) teacher knowledge: CK, PK, and PCK.

General descriptions of PCK in science can be found in literature. Adapted from Magnusson, Krajcik & Borko (1999) the construct contains:

1. Knowledge of science curricula and objectives,
2. Knowledge of students' misconceptions, difficulties and typical mistakes,
3. Knowledge of representations and analogies to facilitate students' learning of specific issues,
4. Knowledge of science-related strategies for instruction and
5. Knowledge of science-related diagnostics, assessment and evaluation.

Magnusson, Krajcik & Borko pointed out that PCK includes (1) the ability to align topics for vertical conjunction over the school years and with respect to national standards. Teachers (2) have to facilitate students' science learning based on their cognitive levels. Additionally, teachers should know about difficulties in learning science, reasons for those difficulties and possibilities for overcoming them. Successfully leading science instruction (3 & 4) implicates knowledge about structuring science-lessons and examples, which are suitable to foster students' understanding. This category demonstrates the importance of content knowledge especially well, and obviously also that the junction of PCK and CK remains blurry. At lastly, in order to adequately evaluate science learning, it is (5) necessary that teachers know about what to assess and how they should assess it.

What the different conceptualizations have in common is that they point out facets of (in-service) teacher knowledge without connection to a specific subject or the knowledge-level of teacher trainees. The study should contribute to bridging that gap.

Method

To identify elements of PCK in chemistry teacher education programs, a qualitative interview study will be conducted. The guided expert-interviews will follow developed manuals. Two different groups of experts will be brought in: teacher trainers at university (who are educational researchers as well) and teacher educators at school, who are supervisors of pre-service teachers. These two experts groups represent both institutions that are responsible for teacher education, so this is seen as a beneficial combination. The whole sample consists of sixteen interviewees, eight per group. The interviews take 60 to 90 minutes. In order to prepare them for content analysis, all interviews are audio-taped and transcribed. The qualitative analysis basically follows the “analytical hierarchy” that can be seen as a conceptual scaffolding according to Spencer, Ritchie & O’Connor (2003, Fig. 1). Starting from raw data, it includes several steps of data management, descriptive and explanatory accounts. The process of analysis is iterative. Moving up and down the stages is possible at any time.

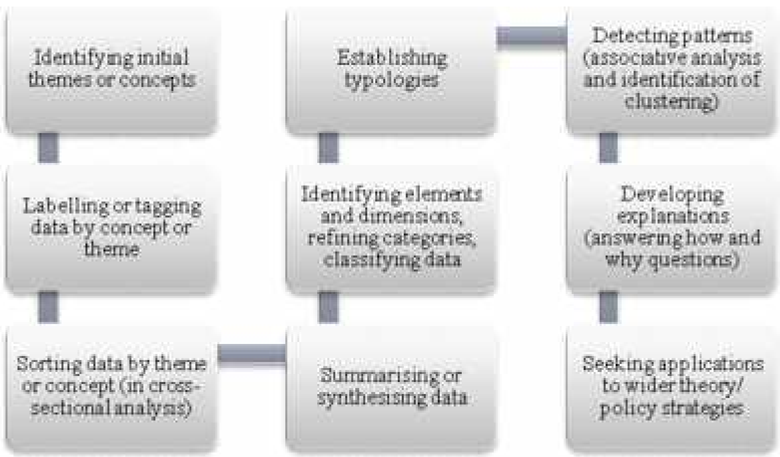

Figure 1. The Analytic Hierarchy, according to Spencer, Ritchie & O’Connor (2003). P. 212

Beyond analyzing the interviews case-by-case, this analytical hierarchy enables a cross-sectional analysis (analysis across different cases) at an early stage in order to aggregate the statements concerning a specific category of the different interviewees. For this reason the approach is attractive to this project. The first steps of data-management aim to develop a category system that provides the basis for further analysis. However, to acknowledge previous findings, the category system will not be based solely on the interview data. Theory-driven general facets of science PCK (compare Magnuson, Krajcik & Borko, 1999) constitute the main categories. Inductively developed subcategories represent chemistry-specific clarification. The constituent elements of university PCK for prospective chemistry teachers (which will be identified after the analysis of the interview data) will be presented to another group of teacher educators, namely educational researchers. They will be asked to rate the relevance and practicability of these elements to examine content validity and to ensure that only shared facets will be chosen for a following test-construction. The operationalization of approved facets will generate test-items in order to measure reflective PCK of prospective chemistry teachers.The analysis process has not yet been completed, but the results that will be published in the paper basically refer to the five steps shown in Figure 2.

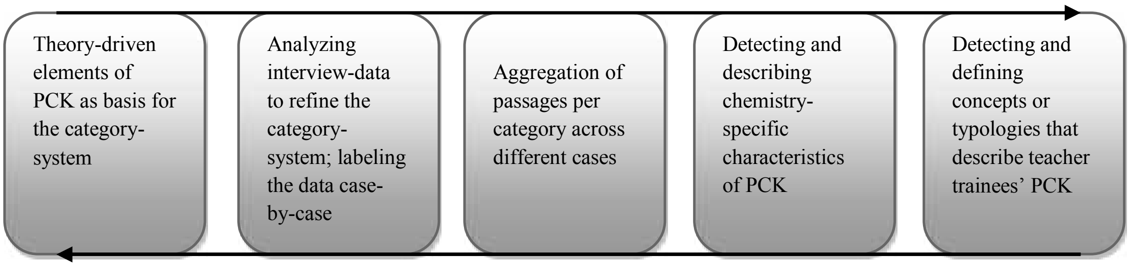

Figure 2. Iterative steps of interview-analysis

These five steps of analysis that are explained in the boxes describe the modification of the original process according to Spencer, Ritchie & O'Connor and its application for this project. The second box, for example, sums up steps one and two of the original work; the fourth box represents steps four to six of the analytical hierarchy. The chosen method helps call out the common facets of the PCK construct, which possess a more global quality. Applying them case-by-case in the analysis of the interview-data leads to an individual interpretation of chemistry-specific PCK. Interviewees were asked to use examples to explain their interpretation of PCK so the case-level is maximally personalized. In order to derive facets of chemistry-specific PCK-themes or -concepts for teacher education programs, it is necessary to abstract from particular cases. The results of the cross-sectional analysis can be placed between the global and the individual descriptions of the PCK construct. Figure 3 visualizes this process:

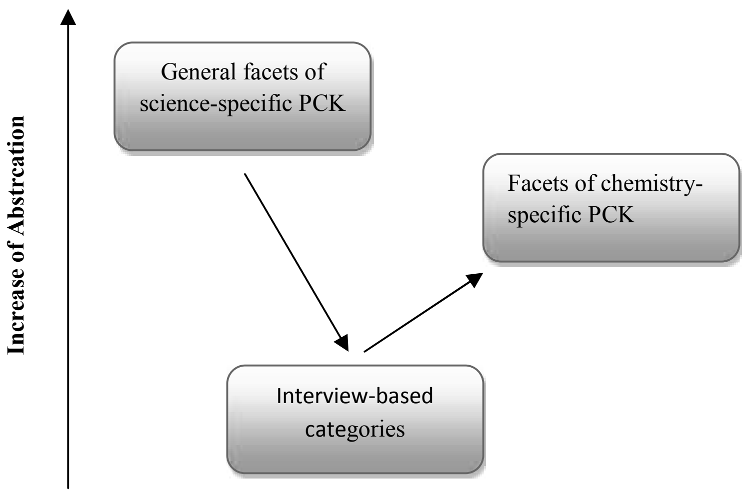

Figure 3. Process of developing a conceptualization of chemistry-specific PCK

Results

At this time, six interviews are being conducted, transcribed, and analyzed. To date, the sample consists of one interviewee who works as a teacher educator at university and five who are teacher educators of the second phase. All interviewees are male. Their work experience as teachers on average is eighteen years, and at least eleven years. Their work-experience as supervisors for pre-service teachers varies from three to nine years (on average 5.8 years). The interviewed supervisors of the second phase of teacher education train pre-service teachers at higher (N = 2, both gained a doctoral degree in chemistry education) and lower (N = 3) secondary schools. The following table provides an overview of some selected results. The columns refer to the first three boxes of Figure 2.

Table 1. Selected results after 6 expert-interviews.

Theory-driven facets of science-specific PCK (adapted from Magnusson, Krajcik & Borko, 1999)	Categories for labeling the interview-data	Chemistry-specific characteristics of PCK
Knowledge of the curriculum and objectives	- Aims of chemistry education: - content-related goals of chemistry education, section of students' competence	Knowledge of the National Educational Standards for chemistry and their implementation during instruction; Knowledge of the spiral development of chemistry issues
Knowledge of students' misconceptions difficulties and typical mistakes	- Examples for chemistry-specific misconceptions - Examples for chemistry-specific learning difficulties	Knowledge of ways to facilitate the understanding of the relationship of macroscopic and submicroscopic issues; Knowledge of difficulties and potential regarding models during chemistry instruction
Knowledge of representations and analogies to facilitate students' learning of specific issues	- Reasons for learning-difficulties in chemistry: spiral curriculum terminology	Knowledge of determining factors for chemistry instruction: criterions for selecting representative chemical issues, methods, and experiments
Knowledge of subject-related diagnostics, assessment and evaluation	- Kinds of measuring students' chemistry competence - Assessing students' experimental skills	Knowledge of possibilities for chemistry-specific assessment
Knowledge of subject-related strategies for instruction	- Suitable methods - Suitable experiments - Practical skills - Examples for successful teacher-acting	Knowledge of ways to implement scientific reasoning and criteria for selecting adequate experiments for instruction: e.g. context / relevance of chemistry issues, institutional possibilities and limitations (adherence of security standards, funding, course-size)

The following explanations refer to the first line of the table in order to exemplify the whole process of data-analysis.

To detect reflective pedagogical content knowledge for chemistry teacher education, the statements of the interviewees were summarized and aggregated into more common concepts. After analyzing the first interviews and abstracting from the individual perspective, results for the general facet knowledge of the curriculum and objectives can be outlined:

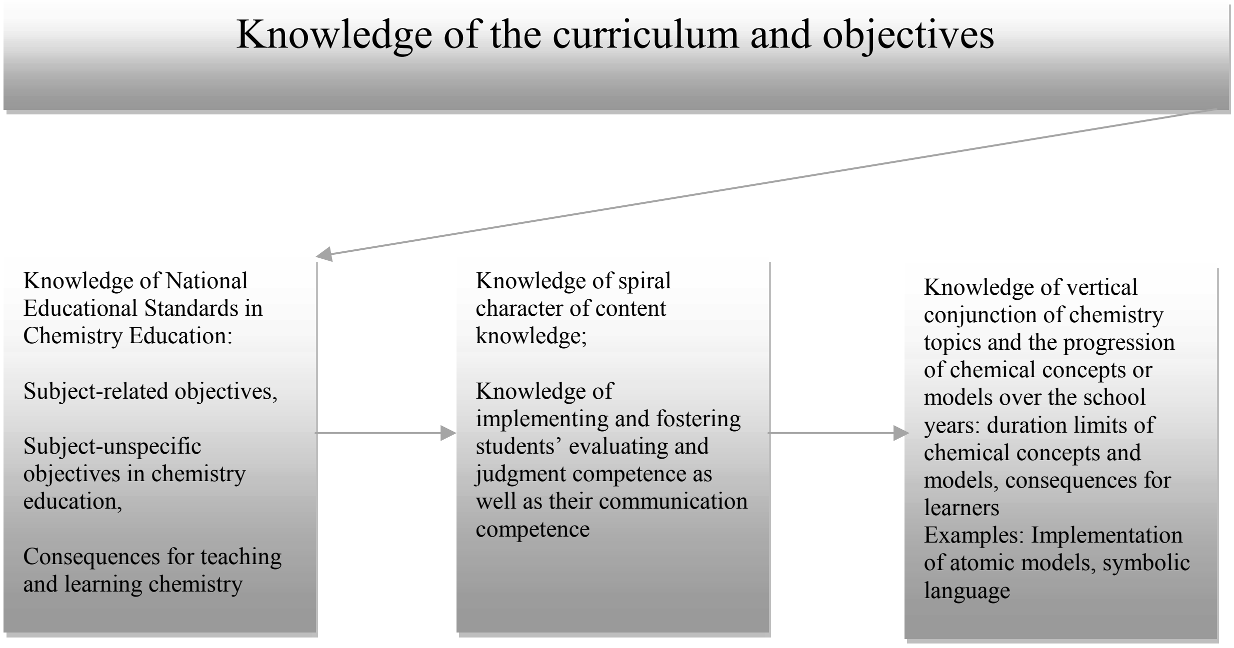

Figure 4. Process of curriculum-development

One facet of prospective chemistry teachers' reflective knowledge is to understand the spiral character of content knowledge and its consequences for structuring lessons. According to the interviewees, prospective chemistry teachers have to be familiar with national curricula in chemistry education, and they have to know about chemistry-specific objectives. In order to distinguish this knowledge from CK, how chemistry issues are introduced and developed during chemistry instruction needs to be stressed. This is important, even if just for the students' perception of the subject. Prospective teachers should be sensitive to and prepared for the reality that students will always need knowledge from previous years, a factor that is less significant in biology, for example. Prospective teachers should not underestimate how this factor could influence students' attitudes towards chemistry. Another aspect that could affect students' interest in learning chemistry concerns the duration limits of chemistry concepts. Knowledge that is imparted at school is temporary, which generates dissatisfaction. Knowing strategies to handle this have to be part of reflective chemistry PCK.

Discussion and options for further research

Because there are still interviews remaining, this paper has focused on the method and the process of data analysis. Nevertheless, first results of six interviews show that it is indeed possible to deduce facets of prospective chemistry teachers' knowledge that should be acquired at university. The chosen method is appropriate for deriving common facets from individual statements. After conducting and analyzing the whole sample, the study will conclude by developing a curriculum for chemistry teacher education programs.

Matching both expert groups of teacher educators creates a valuable, comprehensive view of chemistry-specific PCK -elements and –examples. This clarification of the construct will be the foundation for developing a quantitative PCK test for prospective chemistry teachers. This developed test instrument will be piloted within the presented project. Further projects will then have recourse to the test in order to measure student teachers' outcomes. The evaluation of the impact of teacher education in Germany is one necessary step towards detecting avenues for bigger-picture improvements.

Abstract: The purposes of this study were to describe pre-service science teachers' (PSTs) epistemological word view and science teaching efficacy beliefs and to explore how PSTs' epistemological word view can be predicted from linear combination of science teaching efficacy, taking course relating nature of science (NOS), and the number of teaching method course PSTs took. Epistemological World View (EpWV) Instrument and Science Teaching Efficacy Belief Instrument including personal science teaching efficacy (PSTE), and science teaching outcome expectancy (STOE) dimensions was administered to 68 PSTs participated from two different public universities. Findings revealed that the PSTs' scores about EpWV, PSTE, and STOE were favorable level. The result also indicated that PSTs' personal science teaching efficacy, taking NOS course and the number of teaching method course was significantly contribute to the PSTs' epistemological word view. This model explained the 16,6 percent of variance of the integration scores. Both personal science teaching efficacy and PSTs' taking NOS course had almost equal and positive contribution to explaining the PSTs' epistemological word view. Furthermore number of course dealing with teaching method made the strongest unique positive contribution to explaining the PSTs' epistemological word view. Our research suggested that it should be given importance to the courses related to teaching methods and NOS while application of current teacher training programs in the universities. This approach may improve PSTs science teaching efficacy belief and their epistemological word views, which are the two important factors for students learning and effective teachers' classroom practices.

Keywords: Pre-service science teachers, epistemological word view, science teaching efficacy beliefs, teaching method course, nature of science course

BACKGROUND, FRAMEWORK, AND PURPOSE

There are many efforts to improve teacher education and to overcome some problems in the teacher education (Karagozoglu, 1991). Eight year compulsory education increased universities' pre-service teachers' capacity to educate more teachers and the awareness about the necessity of new strategies in teacher training programs. Therefore, teacher training programs has been changed from different aspects. For example, pedagogical courses were added and the number of methods courses was increased. It was also given importance to teaching skills for effective instruction in method courses (Tekkaya, Cakiroglu, & Ozkan, 2004). In the literature Schraw and Olafson (2002) and Howard, McGee, Schwartz, and

Purcell (2000) emphasized the relationship between teaching practices and epistemological word views. Epistemological world views refer to "teachers' collective beliefs about the nature and acquisition of knowledge" (Schraw & Olafson, 2002, p. 102). Literature reveals three types of epistemological word views namely realist, contextualist, and relativist. Teachers with realist world view transmit fixed body of knowledge to students as passive recipient. Teachers with contextualist word views give more importance to the process of the students' construction of knowledge as facilitator. Teachers with relativist world views create an environment where students can learn to think independently and support the idea about what they know and believe shouldn't really influence their students. In the literature researchers agreed that students and teachers had different epistemological word views that lead to differences in teachers' instruction and students' learning (Schraw, Crippen & Hartley, 2006; Schraw & Olafson, 2006). Teaching efficacy belief is another important factor that influence teachers' effectiveness (Enochs & Riggs, 1990) and student learning and related factors (Woolfolk, Rosoff & Hoy, 1990). Teaching efficacy beliefs include both personal science teaching efficacy referring to perform effective science teaching behaviors and science teaching outcome expectancy referring to behaviors to produce desirable outcomes (Enochs & Riggs, 1990).

The purposes of this study were: (1) to describe pre-service science teachers' (PSTs) epistemological word view and science teaching efficacy beliefs and (2) to explore how PSTs' epistemological word view can be predicted from linear combination of science teaching efficacy, taking course relating nature of science (NOS), and the number of teaching method course PSTs took.

RATIONALE

The new vision of Turkish science and technology program and reform on teacher education program increased the importance of teacher role and beliefs in classroom. Although in all of the universities there is nationwide teacher education program curriculum proposed by Council of Higher Education, design and application of these courses in universities might be different. These differences also might influence pre-service teachers' epistemological word views. Moreover, in the literature there is limited number of studies about pre-service and in-service teachers' epistemological word views (Schraw & Olafson, 2002; Yilmaz-Tuzun & Topcu, 2007). Yilmaz-Tuzun & Topcu (2007) found that teachers' epistemological belief, epistemological world views, and self-efficacy beliefs were related to each other.

METHODS

Sample: To this study 68 PSTs participated from two different public universities. Approximately 84% of the all PSTs in these universities completed all of the survey questions.

Epistemological World View Instrument developed by Schraw and Olafson (2002). This instrument was translated and adapted into Turkish by Yilmaz-Tuzun and Topcu (2007). This instrument included three 5 likert type items assessing three different epistemological word views and these items referring realist, contextualist, and relativist word views.

Science Teaching Efficacy Belief Instrument (STEBI-B) developed by Enochs and Riggs (1990) was used to determine PSTs' self-efficacy beliefs about teaching science. STEBI-B including 23 items 5 likert type instrument consists of two sub-dimensions namely personal science teaching efficacy (PSTE) (13 items), and science teaching outcome expectancy (STOE) (10 items). Reliabilities of these subscales were reported .89 and .76 respectively by Enochs and Riggs (1990). STEBI-B was translated and adapted into Turkish by Tekkaya, Cakiroglu, and Ozkan (2004) and alpha coefficients of these subdimensions were reported .84 and .76 respectively in their study.

RESULTS

Descriptive Statistic: For our first question descriptive statistics on PSTs' perceptions about epistemological word view (EpWV) and science teaching efficacy beliefs were calculated (Table 1). The PSTs' scores about EpWV (M=3.63, SD=.49), PSTE (M=3.99, SD=.34), and STOE (M=3.60, SD=.40) were favorable level. Results were shown in Table 1. In epistemological word view, each scene (item) assesses the different epistemological word view, therefore the percentage of most selected answer for each scene were also calculated to provide information about PSTs' epistemological word view. While 41 PSTs (% 60,3) marked 'I do not agree' option about the scene related to realist word view, 44 PSTs (%64,7) marked 'I certainly agree' option about the scene related to relativist word view. Furthermore, 49 PSTs agreed with the scene related to contextualist word view.

Table 1 *Descriptive Statistic Results*

	M	SD
EpWV	3.63	.49
PSTE	3.99	.34
STOE	3.60	.40

Multiple Regression Analysis: A standard multiple regression analysis was conducted to evaluate how well the PSTs' epistemological word view predict their science teaching efficacy beliefs, whether PSTs' taking NOS course and the number of course regarding teaching method. The result indicated that PSTs' personal science teaching efficacy, taking NOS course and the number of teaching method course was significantly contribute to the PSTs' epistemological word view (Adjusted R^2 =.16, F (3, 67) = 5.449, p= .002). Results were presented in Table 2.

Table 2 *Multiple Regression Results*

	β Weight	Adjusted R^2	F	p
EpWV				
MCourse	.52	.166	5.449	.002
PSTE	.33			
NOS course	.31			

This model explained the 16,6 percent of variance of the integration scores. To examine the way that each independent variable contributed to the model, we looked at the beta (β) values. Both personal science teaching efficacy belief and PSTs' taking NOS course had almost equal and positive contribution to explaining the PSTs' epistemological word view with the beta values β= .33 and β= .31 respectively. Furthermore number of course dealing with teaching method made the strongest unique positive contribution to explaining the PSTs' epistemological word view with the β= .52. STOE did not significantly contribute to the explanation of the PSTs' epistemological word view.

CONCLUSIONS AND IMPLICATIONS

This study revealed that the PSTs' epistemological word views showed difference from realist to relativist. Percentages of the agreement on the contextualist and relativist epistemological word views are higher than that of realist epistemological word view. Since PSTs' views influence student learning in different ways, it is necessary to improve their views and find the factor that related to these views. Also pre-service science teacher had high level of PSTE and also respectable level of STOE but not as high as PSTE. These results might be related to giving more emphasis on teaching methodology and teaching practice in teacher education programmes. In this study, it can be concluded that the more courses related to teaching methods the PST take, the more desirable level of epistemological word views they have. Furthermore, in this study it was found that taking courses which emphasized NOS were likely to make PSTs to believe relativist world view where they support the effectiveness of student-centered teaching approaches. Moreover, the PSTs personal science teaching efficacy positively and highly related to their epistemological word views. These findings might be explained that by the help of these courses, the PSTs may develop beliefs in that they can teach science effectively or find better ways to teach science (high PSTE) and avoid being transmitters of fixed body of knowledge. In other words they prefer to be facilitators for students to construct their own knowledge for themselves. Our research suggested that it should be given importance to the courses related to teaching methods and NOS while application of current teacher training programs in the universities. This approach may improve PSTs science teaching efficacy belief and their epistemological word views, which are the two important factors for students learning and effective teachers' classroom practices.

Abstract: The Physics teachers training has been subject of debates in various fields of research in Education. Among several issues, the articulation between specialized knowledge in Physics and pedagogical knowledge is defended. In Brazil the Ministry of Education established curriculum guidelines for higher education and mechanisms for institutional evaluation composed of different instruments, among them the ENADE (National Exam of Students Performance). Considering that the practices at the University, as well as the practices employed in teacher education in some way are not just influenced by these evaluations, but they also somehow influence on them, we conducted an analysis of the ENADE (2005 and 2008 editions) of the specific degree in physics teaching, in light of the teaching competences highlighted by the Curriculum Guidelines for teachers career. We try to understand the teacher training conceptions in it, as they seek to close the gap between the knowledge of the science to be taught (Physics) and the pedagogical knowledge. The analysis of ENADE showed a predominance of test questions that emphasize the physical content in detriment of educational content and very low occurrence of questions linking the two contents. Thus, although the research in Physics teachers training and the curriculum guidelines suggested interaction between different knowledge and competences, the actual examination to evaluate the performance of pre-service Physics teachers deal with it in a disjointed way.

Keywords: teachers education, Physics teachers, teachers competences, assessment, ENADE.

INTRODUCTION

The debates preceding the adoption of the current Law of Directives and Bases of National Education (LDB) (Law No. 9394, 1996) in Brazil involved a number of discussions closely related to the teachers training. Following approval of LDB, other laws and norms have come to light, such as curriculum guidelines for elementary and high school, and curriculum guidelines for the various careers of Higher Education, among them, the teacher training.

For the Physics teachers training, two national curriculum guidelines were established: Curriculum Guidelines for Undergraduate Courses in Physics (Parecer CNE/CES 1.304/2001) and the Curriculum Guidelines for Undergraduate Courses in Teachers Training (Resolução CNE/CP 1/2002), abbreviated here for CG-Ph and CG-TT, respectively. The establishment of these guidelines led many universities to reshape their curricula, adapting to the new legislation and seeking to incorporate the recent knowledge produced in the in teachers' education researches.

This context is summarized in Figure 1. The gray frames represent the fields in which the research was performed, underlined and bold fonts indicate the Curriculum Guideline assumed as reference to the analysis.

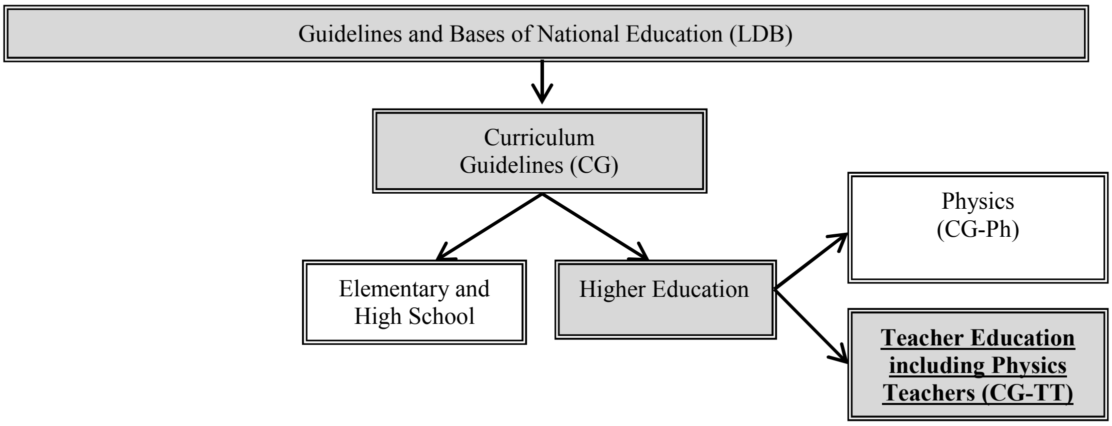

Figure 1: The context of the Curriculum Guidelines for Undergraduate Courses in Teachers Training.

Aiming to complete the cycle of designing and implementing the legislation, besides curriculum guidelines, the Brazilian Education and Culture Ministry established institutional mechanisms for evaluation, organized in the National System of Higher Education Evaluation (SINAES). This system consists of three types of evaluations, among them a student performance assessment, carried out from ENADE (National Exam of Students Performance).

Thus, since this formation is regulated by the guidelines and is subjected to an institutional evaluation through SINAES, it was made an analysis of the ENADE in light of the teachers competences highlighted in CG-TT, in order to understand how the different knowledge and competences are/are not articulated in the Examination which the future physics teachers are subjected. It is necessary to reflect on what it intends to evaluate and what parameters are set for this evaluation. Let us focus the analysis on the factors which indicate needs or opportunities to link physics contents and pedagogical knowledge in teacher education.

TEACHING COMPETENCES

The physics teachers training has been subject of debates in various fields of research in Education. Among several issues, the necessary relationship between the knowledge of the science to be taught (Physics, in this case) and the pedagogical knowledge is a widely discussed and defended issue.

Zimmermann and Bertani (2003), for example, pointed out that researches in this area have pointed the disconnection between the academic content and future teachers expected practices, besides the separation of the specific physics sciences and pedagogical subjects. To Carvalho (2001) the importance of knowing the content to be taught is a consensus among teachers and teacher educators, but it is necessary that the conceptual and methodological knowledge of specific areas are dealt with in an integrated way (CARVALHO, 2001, p. 118).

Related to these aspects, the CG-TT, in its 5th Article, mentions that the school contents must be emphasized in teacher's training in coordination with specific didactics, in our case, the didactics of Physics. In its 6th Article, it describes the various classes of competences that a degree course should seek to develop a student / future teacher:

> *I - competences for the inspiring commitment to the values of democratic society;*
>
> *II - competences related to understanding the social role of the school;*
>
> *III - **competences related to mastering of school contents (our highlight)** to be socialized, and their meanings in different contexts and its interdisciplinary articulation;*
>
> *IV - **competences related to mastering pedagogical knowledge (our highlight)**;*
>
> *V - The competences related to knowledge of research processes that enable the improvement of pedagogical practice;*
>
> *VI - competences for the management of their own professional development. (Resolução CNE/CP 1/2002, p. 3)*

For our specific case, the "school contents" mentioned in the CG-TT refers to the Physics contents.

These competences indicate that it is important that teachers have this plural knowledge, required for their classroom practices. This way, these competences must be indicative for working in undergraduation, as guidelines for the curriculum, as well as in designing evaluations for this undergraduation, once they were legally established by the CG-TT. We emphasize the competences III and IV, which form the basis for the analysis that we carried out on the ENADE.

METHODS

We performed an analysis of some questions that composed the ENADE in 2005 and 2008 editions, applied for undergraduate courses in Physics. The examination is applied to freshmen and seniors, and in a period of four years, it is applied again for the same undergraduation. Every year, the Enade consists of 40 questions::

- 10 Questions: General Knowledge (for students from all courses that are taking part of the ENADE in that year, including both Physics and Physics Teacher Degrees);
- 20 Questions: Specific Contents (Physics) addressed to all Physics students, regardless of the emphasis of the course (Physics or Physics Teacher Degrees);
- 10 Questions: Specific Component:
    - 10 directed only to students in Physics Teacher Degree and
    - **10 directed only to students in Physics Degree.**

We analysed these 10 test questions specifically addressed to Physics Teacher Degree, using as reference the competences mentioned in the CG-TT (National Curriculum Guidelines for Undergraduate Courses for Teachers Training), especially competences III (mastering of scholar contents to be socialized and their meanings in different contexts and its interdisciplinary articulation) and IV (mastering pedagogical knowledge). Once we choosed to analyse two Exams (2005 and 2008 editions), it was analysed 20 questions in total.

Figure 2 resumes this context. The gray frames represent the fields in which the research was performed, and underlined and bold fonts indicate the type of analysed questions.

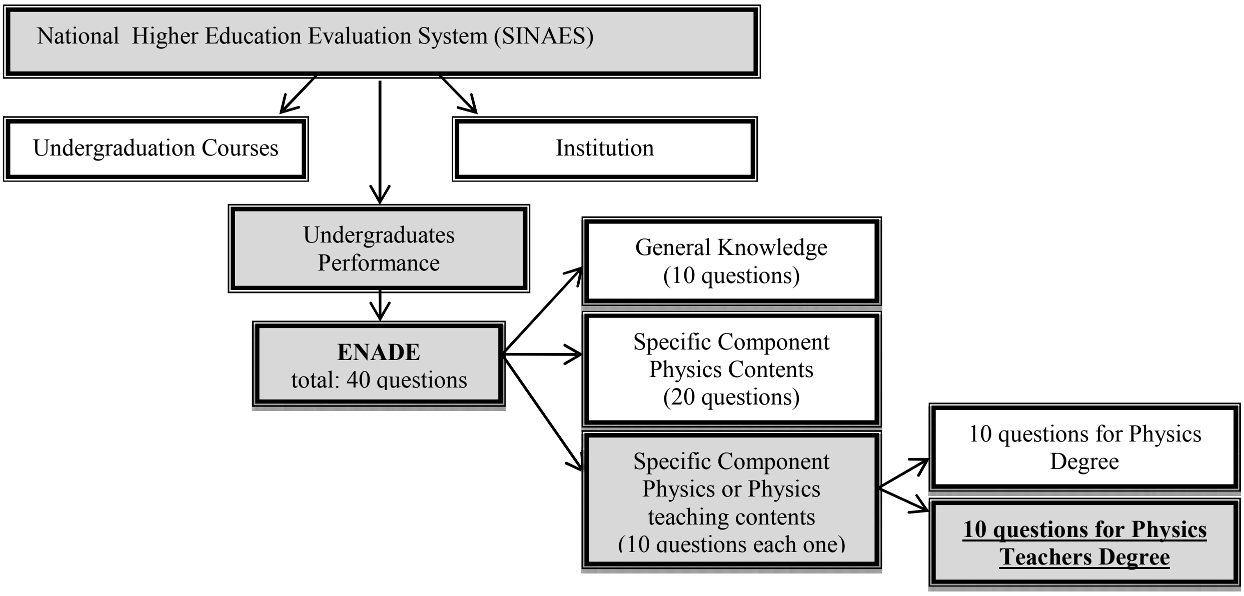

Figure 2: The context of ENADE. Underlined and bold fonts indicate the type of analysed questions

We analysed how, and in how many test questions are made references to a learning physics situation, what is its nature and what competences, those described in the curriculum guidelines, are evaluated in each question. In other words, we searched the presence or evidence of the appreciation of the relationship between science contents knowledge (Physics) and pedagogical knowledge, understanding that this relationship is crucial to establishing the desired relation between theory and practice.

THE ANALYSIS OF ENADE

The analysis shows that the exams consisted of three groups of test questions: Group I - Questions focused on the contents of Physics, Group II - Questions focused on the contents of education (Physics teaching) and Group III - Questions in which Physics and education knowledge are articulated.

It is provided one example of a test question in each group, as follow:

Group I - Focus on the contents of physics science: Test questions whose focus is centered on the assessment of competence "**mastering of school contents**..." i.e. the Physics contents.

> *"The development of educational action from the construction of political-pedagogical projects has become compulsory to schools. In this context, the Physics must be involved, taking the advantage of teaching moments to work their contents. In a hypothetical school, performing a play is one of these moments. Physics teachers decided to work with the Theme 4 of the PCN+: Sound, Image and*

Information. The Physics Project will work with the stage lighting, not forgetting the set designer guidelines. The characteristics of the theatre are: the walls of the stage, when illuminated with mixed green and red light, turn yellow. The floor, when illuminated with mixed green and blue light, is cyan. The colours of the walls of the stage and floor, respectively, are:

A) yellow and blue.

B) yellow and yellow.

C) green and magenta.

D) blue and white.

E) white and white."

In this question it is described an innovative pedagogical situation, to be developed in an interdisciplinary context at school. It provides some details about the activity development, stressing the importance of this kind of teaching methodology in a specific content. However, the question itself is not related to the teaching methodology, it is centred in the Physics content. If the question was composed just using the final part (after "*The characteristics of the theatre are…*"), suppressing all the description of the teaching methodology, it would be perfectly possible to answer the question, just knowing the mixing colours and light of different waves length theories. This way, the question is not addressed to assess the future teacher competence in conceiving or perform this kind of innovative pedagogical activity. So, the main goal of this question is to assess the "*competence related to mastering the school contents...*".

Group II - Focus on the contents of education: Test questions focused on assessing the competence of "mastering pedagogical knowledge". These are questions that relate to specific strategies of physics teaching but do not provide inputs related to the physical content.

"For many years, the exclusive application of long lists of exercises was considered a good strategy to teach physics in high school. Today, it is known that the long lists have limited efficiency.

a) Address the main limitations of this strategy.

b) Propose additional activities to this strategy.

c) Justify the activities mentioned above."

In this question it is assessed the future teacher competences in analysing a specific teaching strategy knowing its limitations, besides their skills to propose complementary strategies. This way, it is addressed to assess the "*competences related to mastering pedagogical knowledge*". Nothing about the Physics contents is assessed in this question.

Group III - Articulation Physics science and education: These are questions that measured the two competences, through the exploration of didactic situations in context in the Physics teaching.

"Recognizing that democratic systems are vulnerable without scientific culture, a physics teacher agreed with the concerns expressed in National Curriculum Parameters (PCN) on the citizen education and the suggestions of curricular changes to be adopted in schools. From this perspective, taking into account the contextual aspects in daily life and History of Science and the epistemological and methodological aspects of Physics Education, describe an activity to be held in a Teaching Unit in the Theme "Universe, Earth and Life", for each skill below.

a) Enhance an "understanding of the current hypotheses, models and forms of research on the origin and evolution of the Universe."

b) Identify ways in which explanatory models of the universe influenced the culture and human life throughout the history of humanity and vice versa."

This question is organized in two items. To obtain the highest grade in this question, the future teacher needs to know not only one specific Physics content (Theories of Universe, related to Earth and Life), but it is necessary to know how to organize a didactic activity, contextualized in the historical, epistemological and cultural aspects that involves this Physics content. So, it is focused on assessing the future teacher in both competences: "mastering of school contents..." and "mastering pedagogical knowledge...".

This kind of analysis was performed to all ten questions for Physics Teachers Degree, for both 2005 and 2008 Exams.

RESULTS

The overall results are summarized in the Table 1:

Year (edition)	**Number of analysed test questions (total)**	**Evaluated Competences**		
		(Group I) Mastering Physics Contents	(Group II) Mastering Pedagogical Contents	(Group III) Both Competences
2005	10	6	3	1
2008	10	4	4	2

Table 1: Synthesis of test questions and competences analysed in the ENADE, 2005 and 2008 editions.

It is observed that mainly in the 2005 Exam it was given prominence to test questions related to mastering the physical content by the physics teacher in training. Secondarily were the test questions related to strategies and methodologies of teaching that could be used in situations of physics teaching. In the 2008 examination, the number of questions designed to assess the physical content is equal to the number of questions designed to assess the field of educational content. However, it is possible to question this figure, once the domain of physical content has been evaluated in those 20 Component Specific test questions, answered by all undergraduates of Physics, independent of professional emphasis (BA or BS). The results also stress issues that test questions of Group III, which we consider important for an integration of theory and practice, were rarely present in the exam, and the greater emphasis was on test questions dealing with physical or educational content in an isolated way.

We are not considering that the questions which compose the exam are inadequate, but that the exam, as a whole, bringing matters only in certain content over others, shows a certain conception of teacher training, dissonant to that recommended in research on physics teachers education and the CG-TT, in respect to relations between the physics content and pedagogical knowledge.

CONCLUSIONS

From the analysis carried out with the ENADE tests it was possible to see that there is a tendency of teacher education in which the knowledge were presented disjointed from each other. We realize that the test questions in general are focused on competences related to the domain of content of physics or competences related to the domain of pedagogical knowledge, in isolation.

Noting the difficulties present in the physics teachers training described in the researches, and curriculum guidelines to teachers education, we observe that it is necessary to reach an issue that isn't yet present in the physics teacher education, related to their own legislation and institutional evaluation.

Facing these results, one must still question the concept of teacher evaluation model present in these analysed documents and the implications in the setting of teaching in higher education and the possibilities to bring changes in the current teacher training model.

WORKING WITH THE MICROSCOPE AS A PROBLEM SOLVING PROCESS

Lissy Jäkel[1]
[1]Heidelberg, Germany

Abstract: A commonly used model of scientific method competence, e.g., experimentation, includes the following dimensions: lab work, scientific inquiry and nature of science. Working with the microscope has to be seen not only as a technical part of lab work. It is another demanding skill of acquiring knowledge in Biology. A better understanding of the influencing factors is required to promote the appropriate use of microscopes in schools. We assume that microscopy as a special problem solving process increases the motivation. We have developed and evaluated teaching units for pre-service student teachers. A short questionnaire for the measurement of intrinsic motivation (Ryan & Deci 2000) was employed. In addition, all participants were asked to assess their interest in various areas of biology and their own skills in microscopy. The study consist of two sub studies in 2010 (n=243) in courses of human biology. The students often could decide themselves, which problem solving method they prefer. During the treatment with a higher degree of self-determination, there was a positive development of interestedness. The values of the respective interest and self-determination are highly correlated. Our investigations within the groups of students give first hints on how the skills to use the microscope for problem solving can be promoted. The positive factors must be considered in the development and testing of training modules for schools.

Keywords: scientific method competence, microscopy, motivation

THEORETICAL BACKGROUND

The skills of gaining knowledge are of central importance for science education.
A commonly used model of scientific method competence includes the following three dimensions: *lab work* (practical work), *scientific inquiry*, *nature of science* (Bayrhuber et al. 2007, Kremer, Urhahne & Mayer 2007). The Scientific Discovery as Dual Research model by Klahr (2000) also focuses on three dimensions of experimentation (*analysing data*, *planning experiments*, *recognizing hypotheses*). Working with the microscope has not only to be seen as a technical part of lab work but also as another demanding skill of gaining knowledge in Biology. Many authors point to the possibilities of microscopy for research-based learning. But few studies exist so far on the frequency or the level of the use of microscopes in the classroom (e. g. Vogt et al. 1999) and the effects of interventions on motivation and skills.

RATIONALE

The intention of the study is to develop a strategy for the development of student’s ability to use microscopes as instruments for problem solving. Student Teachers often take the view expressed; scientific knowledge is best learned by heart and tested in exams. To promote the appropriate use of microscopes in schools a better understanding of influencing factors is required. How can teachers be supported in order to work better and more often with the microscope? The interests of future teachers to do research with the microscope should be strengthened. We suspect that microscopy as a special problem-solving process increases motivation.

Our model of development of competencies in terms of working with the microscope contains the following steps:
level 1- basic practical knowledge about the use of the microscope;
level 2 – the conviction of the usefulness of the application of the microscope in different situations;
level 3 - the use of the microscope specifically to clarify scientific phenomena (*scientific reasoning*);
level 4 - an appropriate use of the microscope in Biology is associated with a clear understanding of the cell concept of living beings (*epistemological views*).

METHODS

We developed and evaluated units for pre-service student teachers focused on the fostering of students' competencies in discovery with microscopes.

A short questionnaire for the measurement of intrinsic motivation was applied. This short scale of intrinsic motivation is a version of the "Intrinsic Motivation Inventory". It represents the factors interest/enjoyment, perceived competence, perceived choice and pressure/tension (5 –point Likert Scale, 5 agree completely, 1 disagree).

The main study consisted of *two sub-studies* which were conducted in *summer* and in *winter terms 2010* in 3 respectively 5 Biology courses of Human Biology for pre-service student teachers. *All measurements were repeated in summer 2011 (n=65) with the following course, but with another instructor.*

In the *pilot sub-study*, student teachers were introduced to microscopy over one semester in two different treatments (n=69). The two versions differed in the degree of self-determination. The internal consistencies for the short inventory of interest range from Cronbachs' alpha = .704 to .867 (10 items).
In the *second sub-study* in winter term 2010 (n=174, age median 21), the instructions for setting the learning pathway were reduced in all five groups. The units were modified in some parameters, e. g. in the frequency of use of the microscope. Courses 1 and 2 were run by the same person *(Results: Figure 1),* courses 3 to 5 by another person. On each day of the course all students were asked to complete a short questionnaire on intrinsic motivation and estimate how long they worked with the microscope *(Results: Figure 1, Table 3).* The internal consistencies for the short inventory of interest range from Cronbachs' alpha = .727 to .861 (9 items).

In a preliminary test, all students were asked to assess their own skills in microscopy, and they were asked to assess their interest in various areas of Biology (Table 2), and their knowledge of some technical terms (*Erythrocyte, Alveolar, Pituitary glands*, white matter, and so on).

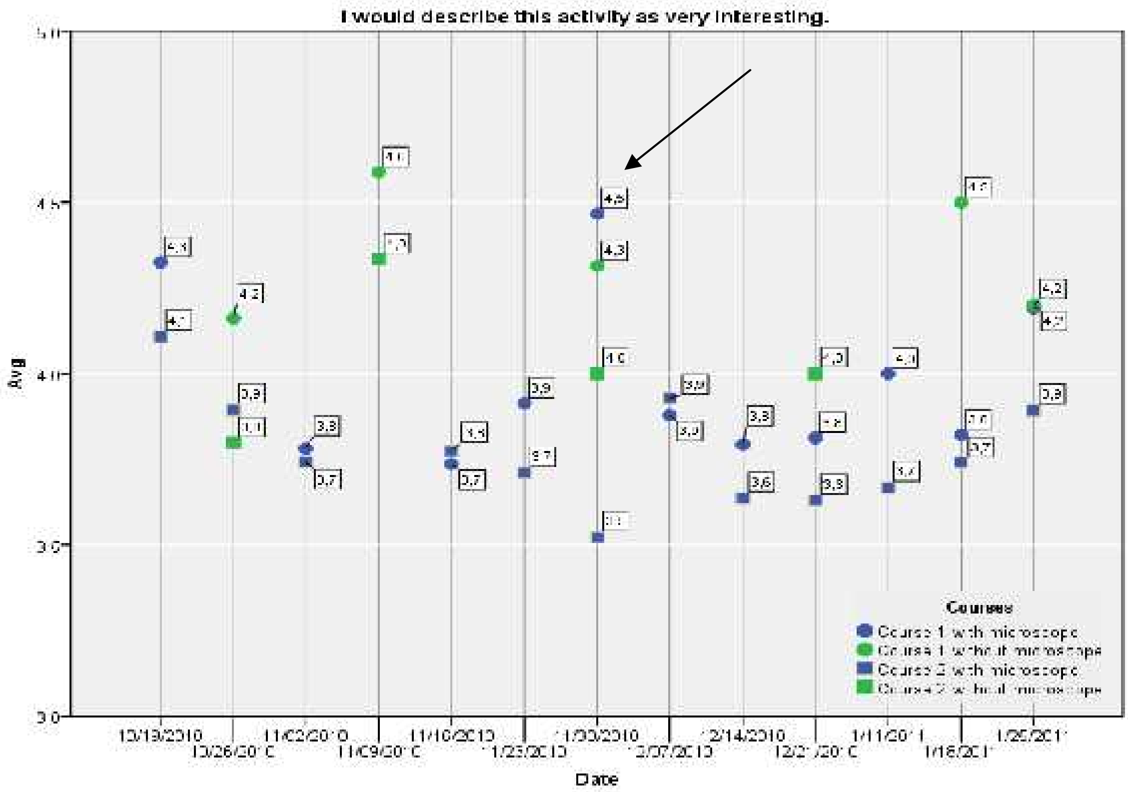
Table 2: Pre-service student teachers´ interests in various areas of Biology

During the first sub-study (summer 2010) a higher degree of self-determination showed positive effects on motivation and interest. When the students worked too often with the microscope, their motivation decreased. The requirement that they draw the observed objects is one reason for the fall in motivation.

Results of the second sub-study (winter 2010) show that motivation during microscopy is high, if lab work is included in problem solving processes and lab work has a high level of self determination. As an example, Figure 1 shows the participants' assessment of interest during winter term 2010.
In November 30th, e. g., they solved problems with the inner ear and with the skin. They had to find out if the "Reissner" membrane consists of one or two layers of cells, and in which layer of the skin there are receptors.

Fig. 1: Motivation during lab work and problem solving

The students often could decide themselves whether they would like to use the microscopy or use another method to discover a scientific problem (*with microscope / without microscope*).



The assessment of the success of their own work correlated significantly with the opportunities for self-determination (Table 3).

The values of the respective interest and self-determination are also closely correlated.

Group 1 and 2 (n=66) winter 2010	Nov.30th perceived competence	Nov. 23rd perceived competence
self determination	.482**	.655**
time which was spent with microscopy	.225	.108
felt pressure	-.544**	-.512**
interest	.413**	.636**

Table 3: Examples for coefficients (Spearman's Rho) for the participants' assessments

However, there is no measurable correlation between the amount of time that was invested in the work with the microscopes during the courses, and the motivation of students.
The perceived burden of the work correlated negatively with the motivation. The students gave the final examination as reason.

There are significant correlations (Spearman's Rho, n=18, oral test / questionnaire) between self determination of one's own knowledge and real knowledge of scientific technical terms (for instance Erythrocyte .493*; Nephron .686**, Alveolar .686**). These results were confirmed in summer 2011.

CONCLUSIONS AND IMPLICATIONS

We are surprised at the information students gave us about their school experiences with microscopy. The students usually assessed their abilities in microscopy in the questionnaire only as mediocre. But in the assessment of the student teachers the microscopy is the learning activity which was more frequently carried out in school than other active and practical learning activities like planning experiments or dissecting organs.

Many students reported that they disapproved of using microscopes especially microscopic drawing. We have to take into account the well-known fact from interest research that school lessons where the topic is frequently re-visited mostly result in less interested pupils.

Where does a single cell begin? Many research participants spoke about their difficulties in orientation between tissues und cell structures. In addition - it seems that there are different types of learners.

Our investigations within the groups of students give first hints on how the skills to use the microscope *for problem solving* can be promoted and how a long-term relationship between person and object could be developed. Students need repeated positive experiences through the use of the microscope.

A "CLASS DIARY" FORUM TO IDENTIFY PEDAGOGICAL THINKING CHANGES IN PRESERVICE SCIENCE TEACHER TRAINING

Jiménez-Liso, M.R.[1]* *& López-Gay, R.*[1]
[1]Departamento de Didáctica de la Matemática y de las Ciencias Experimentales
Universidad de Almería
*Corresponding author: mrjimene@ual.es

Abstract: The purpose of this study is to analyse the incorporation of the pedagogical contents that were learnt among the messages sent by the students to the class diary forum, and identify the meaningful moments of the shared reflexion process during the implementation of a subject called Learning and Teaching Physics and Chemistry (12 ECTS) in the first year of the Master's Degree Initial Secondary Teacher Training.
We can identified some categories about the meaningful moments of the student shared reflexion process and about references of the students to some pedagogical contents as alternative conceptions, models, problem solving, etc. The lack of references to the scientific contents within the first sessions points out that the pedagogical content was not within their cultural knowledge before the teaching but, after it, the use of these terms were more frequent and it reveals the epistemological and pedagogical thinking changes.

Keywords: Preservice Science Teacher Training; Online class diary forum; students' messages analysis; students' messages analysis; epistemological thinking changes

BACKGROUND

There are a lot of factors that researches highlight in the initial training of science teacher (Loughran, 2007). Among all of them, we will focus on the scientific dimension in order to promote changes in concepts of teachers in the initial training, and to help in the development of ideas, theories, principles, and scientific models more sophisticatedly. Therefore, we enshrine within the development of the pedagogical content knowledge (Berry et al., 2008). This is essential because future teachers will develop: teaching strategy knowledge, understanding the student knowledge, assessing the student knowledge, and knowledge about (purposes) aims and objectives of the topic within the curriculum (Hence et al. 2008).

FRAMEWORK

The present study was developed during the first year of the Master's Degree Initial Secondary Teacher Training (12-18 years old students) in Spain. It was enshrined in the implementation analysis of a subject within the specific module, specialty Physics and Chemistry, called Learning and Teaching Physics and Chemistry (12 ECTS)[1]. This subject had 25 presential sessions of 2.25 hours each last academic year (2009-2010), and it had the following scientific-didactic topic distribution (Table 1).

[1] This specific module also contains a subject called Teaching Innovation and Educational Investigation (6ECTS) which is directly related to the application module (Practicum), and another subject of disciplinary education complement within the specialty (6ECTS).

Sessions	Content
1	Introduction Science Education Aims
2 3	Impediments to change, Spanish National Standards
4	Talking Science Communicative Approach
5	Formative Evaluation in Science
6 7 8 9	Forces and Movements
10 11 12	Models: Sun-Earth
13	Model of parts
14 15	Chemical Change; Acid-Base Models
16	Nature of Science
	Scientific Literacy
17	Problem Solving
18 19	ICT and Science Museum
20 21	Problem Solving
22 23	Practical Works
24	Teaching & Learning models in Science
25	Final Evaluation

Table 1. Content distribution by sessions

The first three sessions were about the problematization of the subject and they were focused around the question "what should a Physics and Chemistry teacher know and be able to do for their 12-to-18-year-old students to learn properly?" The remaining sessions were organised around some blocks of scientific content, since these contents are fresh for the recently graduates and they allow to recognise easily a common thread. In table 2, for each curricular block (scientific content) we show which didactic contents (1-8)[2] could be introduced more carefully (the shady cell shows the block where each science education contents would be covered more carefully).

Scientific content / Pedagogical content	1	2	3	4	5	6	7	8
Sun-Earth Model	X	X			X	X	X	X
Force and Movement	X	X	X	X	X	X	X	X
Properties and structure of matter	X	X		X	X	X	X	X
Energy, transfer and changes	X	X	X	X	X	X	X	X
Chemical Change	X	X	X	X	X	X	X	X
Light and sound	Not implemented for lack of time							

Table 2. Didactic contents developed in each curricular block

Therefore, this organization belongs to an integrated approach between the content and the didactic knowledge. However, it is not only because the didactic knowledge is always based on specific scientific content, but also because among our purposes it is that the Master's Degree students use this opportunity to question, revise and increase their content knowledge.

PURPOSE

Among the activities organised in order to complete the remaining credits online (45h), it is the forum called "class diary". It encourages a collective reflexion process, parallel to the development of the presential sessions. In this forum, open for that aim within the virtual classroom (platform webCT), at the end of each session, the student responsible expressed a brief narrative summary, and not only schematic. In the initial instructions the students were asked to be subjective in their comments, *because they did not have to create an objective and*

impartial report, but to reflect loudly on the knowledge and development of the sessions on classroom.

The purpose of this study is to analyse the incorporation of the didactic contents that were learnt among the messages sent by the students to the forum, and identify the meaningful moments of the shared reflexion process.

METHODS

The virtual platform used in our university allows us to download the messages grouped by sessions, and also to analyse them with a CAQDAS afterwards: computer assisted qualitative; where it can be identified the following categories (table 3) about the meaningful moments of the student shared reflexion process.

About references to the didactic contents:	About the meaningful moments of the reflexion process:
1. Models 2. Talking Science 3. Doing Science 4. Problem Solving 5. Alternative conceptions	1. Epistemological change of thinking 2. School biograhy reflexions 3. Didactic change of thinking 4. Autoregulation moments 5. Formative demands

Table 3. Categories Analysis

RESULTS

In the figure 1 we show the frequency for each didactic contents category, distributed by those sessions in table 2 and identified in the messages sent by the students (N=170) in 22 sessions. It was reduced to 22 because the sessions 18 and 19 did not have diary due to the visit to a science museum and the work with the ICT required more time than the established (10h).

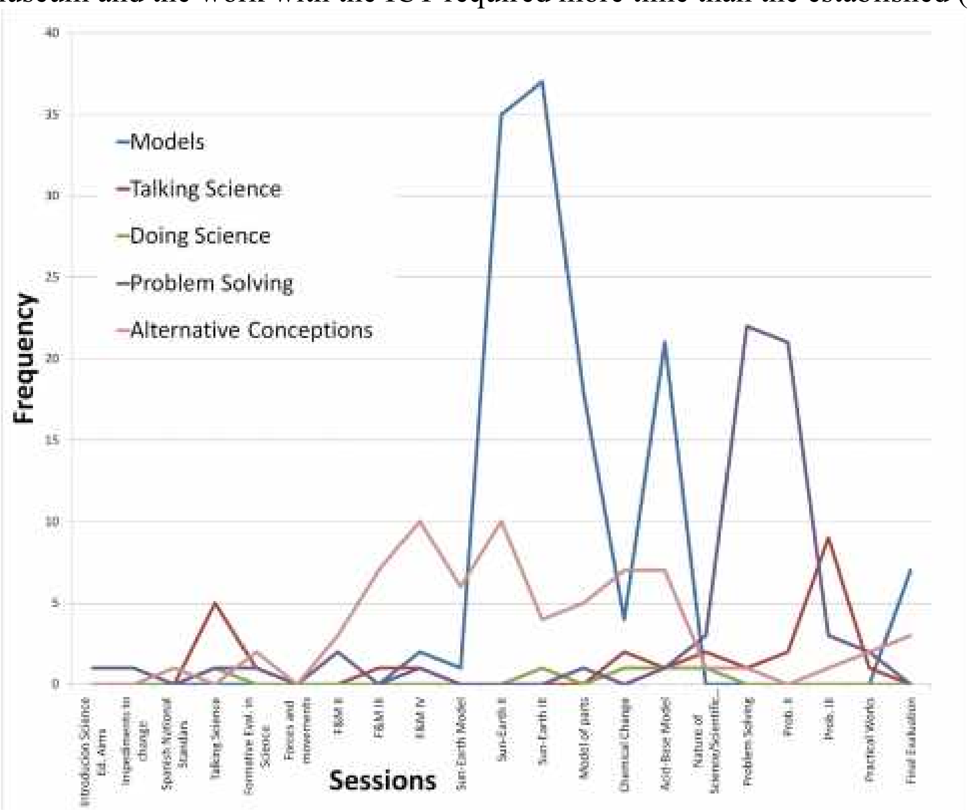

Figure 1. Frequency for each category-II, distributed by sessions

a. Models

In almost all the didactic contents category, the higher frequencies coincide with those sessions related to that didactic content.

The lack of references to the scientific models within the first nine session points out that this didactic content was not within their cultural knowledge. The content appeared from sessions 11 and 12, where they learnt the model Sun-Earth (López-Gay & Jiménez-Liso, 2010). Sessions 13 to 15 were focused on school chemistry models; the use of the term "model" was more frequent. In the last sessions (24 and 25), the messages have been mostly to recognise their pedagogical thinking change; therefore, references to the models are used as a revision of the achieved aims: *the contents have been selected according to the alternative conceptions, and to the big development that they present*.

When experienced in first person the existence of alternative conceptions, the effectiveness of models to explain and predict phenomena, and the innovation experiences presented, it is questionable the necessity of changing the reality in science classrooms: *unfortunately the teaching method is very similar to the one we received and science is not "squeezed" to the maximum, let's see if we change it a little bit...* However, they still recognise a small resistance to the didactic change of thinking: *unwittingly, I insist on keeping approaching the learning process how I was taught*. It expresses the weight of the school experience as an obstacle for the change.

b. Talking and Doing Science

The term 'talking science' only appear in the students messages when specify it on fourth session. However it is present in the majority of the messages through the other sessions and students put special emphasis on it at the end of the course when Problem solving was dealt.

c. *Alternative Conceptions*' data (fig 1) indicates that this term is present in the messages after all the sessions in spite of only we work on it in two of them (forces and movement) and (Sun-Earth model). Students usually specify as self-regulated moments: In this case, we didn't need a pre-test to be aware of alternative conceptions that we have got about this subject (Sun-Earth Model first session).

d. Scientific and Pedagogical Contents as a whole (PCK Integrated model)

When experienced in first person the existence of alternative conceptions, the effectiveness of models to explain and predict phenomena, and the innovation experiences presented, it is questionable the necessity of changing the reality in science classrooms: *unfortunately the teaching method is very similar to the one we received and science is not "squeezed" to the maximum, let's see if we change it a little bit...*. However, they still recognise a small resistance to the didactic change of thinking: *unwittingly, I insist on keeping approaching the learning process how I was taught*. It expresses the weight of the school experience as an obstacle for the change.

CONCLUSIONS AND IMPLICATIONS

Very often researchers that teach in the initial training of science teachers, we make out some indications that highlight that our students are learning how to be reflexive teachers or, on the contrary, the difficulties that they still have. The big majority of these indications can be obtained within the messages our students sent to the forum "class diary". In this study, we have been able to analyse and prove those indications, and identify the key moments where pedagogical and epistemological thinking changes happened.

SUBJECT KNOWLEDGE AND PEDAGOGY IN PRE-SERVICE SCIENCE TEACHER TRAINING COURSES IN ENGLAND AND WALES

Roger Lock[1] *and Allan Soares*[1]
[1]School of Education, University of Birmingham, Edgbaston, Birmingham, B15 2TT, United Kingdom.

Abstract: The aim of the research reported in this paper was to explore the extent to which subject knowledge and pedagogy are addressed in one year pre-service science teacher training courses in England and Wales. The study employed a mixed methods approach with progressive focusing between the research instruments. The methods used were document analysis (n=81), university tutor and pre-service teacher questionnaires (n=72 and 245 respectively) and telephone interviews (n=8 and 22 respectively). The main conclusion drawn from the part of the study reported here is that a majority of courses prepare pre-service teachers to teach pupils all three sciences to 16 years. In addition, the minimum degree requirement Higher Education Institution tutors expect for a biological science pre-service teacher is higher than for a physical science pre-service teacher. Nearly one third (31%) of pre-service teachers who categorise themselves as physicists have a degree with minimal or no physics content. One year pre-service teacher training courses do not have sufficient time to equip newly qualified teachers to teach across the sciences to pupils aged up to 16 years and, consequently, there is a need to raise awareness for policy makers and senior managers in schools that continuing support for subject knowledge pedagogy is needed for newly qualified and early career science teachers.

Keywords: Pre-service teachers, subject knowledge, pedagogy

BACKGROUND

Pre-service science teachers on a one year initial teacher training (ITT) course usually have a first degree in some aspect of either the biological or the physical sciences. In many cases their undergraduate study is likely to have been part of a 'pick and mix' modular degree programme which can leave them with a narrow knowledge base of what might be regarded as their specialist subject: biology, chemistry or physics. Few pre-service teachers will have studied all three science subjects to advanced level (18 years). Many may have only studied one science to advanced level and, for these pre-service teachers their study of other sciences will have been limited to general certificate level (16 years). Studies by Lock and Soares (2005), Lock, Soares and Foster (2009) and the House of Commons Children, Schools and Families Committee (2010) suggest that schools require many newly qualified teachers (NQTs) to be competent to teach all sciences to general certificate level. This places a considerable demand on pre-service teachers developing their subject knowledge and ways of transforming this knowledge into effective teaching during a one year ITT course. Even in teaching their subject specialism, pre-service teachers need pedagogical content knowledge to transform good subject matter knowledge into effective lessons (Van Driel, De Jong and Verloop, 2002; Kind, 2009).

A report from the Science and Learning Expert Group (Department for Business Innovation and Skills, 2010) stresses the importance of providing subject-specific training in ITT, specifically recommending that there should be further investigation into:

> *'..the consistency between initial teacher training* [ITT] *providers in the balance between subject-specific and general pedagogical training to ensure that subject-specific pedagogical training receives a high priority.*' (Recommendation 4, p10)

Our research is therefore timely in that it addresses training in subject knowledge and pedagogy in one year pre-service science teacher training courses in England and Wales.
The aims of the research were to explore:

- the extent to which subject knowledge and pedagogy are addressed on one year Science ITT courses
- the ways in which the pre-service teachers acquire and use this subject knowledge and pedagogy
- the extent to which the subject specific course elements meet pre-service teachers' perceived needs for the NQT year.

RATIONALE

Developing into an effective teacher, of say physics, requires more than just the knowledge and understanding of physics content and the generic pedagogy that is applicable to a teacher of any subject.

> *'...just knowing the content well was really important, just knowing the general pedagogy was really important and yet when you added the two together, you didn't get the teacher'*
> (Shulman in an interview reported in Berry, Loughran and van Driel, 2008)

This suggests that a graduate of a particular subject is only likely to start the transformation into a teacher of that subject when they begin to consider how best to teach the subject content in order to make it learnable by others. To account for this, Shulman (1986) introduced the term Pedagogical Content Knowledge (PCK) and proposed that such considerations included analogies, illustrations, examples, explanations, and demonstrations.

While teacher educators and researchers agree that PCK is a useful construct (e.g. van Driel, Verloop and de Vos, 1998; Loughran, Mulhall and Berry, 2008; Kind, 2009), it is also acknowledged that there are differences in its definition and conceptualisation (Nilsson, 2008). Nevertheless, even though PCK appears to be a common component of the teacher knowledge needed to be an effective teacher of a subject (van Dijk and Kattmann, 2007; Nilsson, 2008), it is not a commonly used term by teachers.

Loughran, Mulhall and Berry (2008) proposed a framework called *Content Representations* (CoRes) – key content ideas, known alternative conceptions, known points of confusion, ways of framing ideas to support learning, ways of testing for understanding; and '*Pedagogical and Professional-experience Repertoires'* (PaPeRs) – specific aspects of teaching the topic to explicitly introduce PCK to beginning teachers.

Geddis (1993) proposed that developing teachers need to address pedagogical issues that are content-specific which suggests that to be an effective teacher of physics it is necessary to not only know the content of the various topics (e.g. forces, energy etc), subject knowledge of the topic, but also '*...the particular teaching and learning demands of that particular topic'* (Bucat, 2004, p 217), topic specific PCK.

METHODS

The study employed a mixed methods approach (Tashakkori and Teddlie, 2003) with progressive focusing between the research instruments (Hammersley, 2006). The methods used were document analysis, university tutor questionnaires and telephone interviews and pre-service teacher questionnaires and telephone interviews.

All research instruments were piloted and trialled and the internal consistency of responses and reliability of researcher analysis were investigated where appropriate. The research has been conducted in a thorough and rigorous manner.

Science education tutors (n=160) from 64 universities in England and Wales offering a one year ITT course in science, including biology, chemistry, physics and geology (GTTR, 2009) were informed of the purpose of the study and invited to send course documentation for analysis. Eighty one documents were received from 24 HEIs. This return was representative in terms of geographical spread, type of institution, key stages addressed and science specialism. The documents were analysed for subject-specific training in both the universty and school-based parts of the courses.

Of the 160 university science education tutors, 134 found to be actively engaged in one year ITT courses were invited to participate in an on-line questionnaire. The response rate was 54% (n=72) and tutors from 33 universities voluntarily identified themselves and their institution as willing to be involved in phase 2 of the research. In this second phase tutors (n=8) from six case study universities were selected for interviews and helped to facilitate the completion of the questionnaire by their pre-service teachers (n=245). In each of the six universities up to four pre-service teachers were interviewed by telephone (n=22) having indicated in questionnaire responses that they were willing to participate further. Pre-service teacher questionnaires were administered at the end of ITT year and then interviews conducted in the period leading up to the start of their NQT year.

RESULTS

Selected results from the university tutor and pre-service teacher questionnaires and interviews are presented here.

Data in Table 1 show that most courses (58%) prepare pre-service teachers to teach pupils all three sciences to 16 years. This meets the expectations of many schools and is, in part, made necessary by the shortage of physics and chemistry graduates entering pre-service training.

In an attempt to increase the recruitment of physical science graduates who chose to enter pre-service science teacher training, the minimum class of degree required for physical science graduates appears to be lower than that for biological science graduates (Table 2). Over 50% of university tutors are prepared to accept physical science pre-service teachers with a third class degree or less, whereas only one-third of tutors are prepared to accept these classes of degree from biological science pre-service teachers. This could have serious implications for the proposal to cease funding for applicants with degrees lower than a 2.2 classification (DfE, 2010a) and is likely to reduce even further the supply of physical science teachers.

Training to teach Biol & Chem & Phys to 11-14 year old pupils and…	**n**	**%**
Biol **or** Chem **or** Phys to 14 -16 year olds	6	8
Biol **&** Chem **&** Phys to 14 -16 year olds	11	15
Biol **or** Chem **or** Phys to 14 -18/9 year olds	21	29
Biol **&** Chem **&** Phys to 14 -16 year olds Plus specialism (P/C/B) to 16-18/9 year olds	31	43
Other	2	3
No response	1	1

Table 1. Course content for pre-service teacher training. (Tutor questionnaire)

Minimum class of degree required by university tutors	**Biological science pre-service teachers n (%)**	**Physical science pre-service teachers n (%)**

First	0 (0)	0 (0)
Upper second	6 (8)	0 (0)
Lower second	35 (49)	26 (36)
Third	18 (25)	29 (40)
Ordinary	6 (8)	11 (15)
Other	4 (6)	4 (6)
No response	3 (4)	2 (3)

Table 2. Minimum class of degree required by university tutors for biological and physical science pre-service teachers.

Although 79% of tutors regard class of degree as important (Table 3), tutor interviews revealed that other personal qualities and experiences also contribute to the makings of a teacher and led to offers of places on pre-service teacher training courses to applicants with third class degrees or lower.
Forty-two per cent of HEI tutors regard the institution awarding the degree as unimportant. This finding contrasts with the Government White Paper's apparent focus on good quality graduates from top class universities training to become teachers (DfE, 2010a)

Expectation	Yes	No	No response
Degree class unimportant	15 (21)	57 (79)	0
Institution awarding degree unimportant	30 (42)	42 (58)	0

Table 3. Pre-course subject knowledge expectations (n, % in parentheses).

Nearly a third (31%) of pre-service teachers who categorise themselves as physicists have a degree with minimal, or no, physics content. Data from the pre-service teacher questionnaires show graduates with degree titles that include: psychology, applied microbiology, environmental management, archaeology, forensics and psychology and sports science, training to be teachers of physics.
Evidence from interviews and the document analyses indicates that approaches to addressing subject knowledge and pedagogy are very variable, ranging from no formal support to teaching sessions dedicated to the subject knowledge and pedagogy associated with specific topics such as electricity, photosynthesis and the periodic table.

CONCLUSIONS AND IMPLICATIONS

The main conclusions from this study are that:

- Most courses for pre-service science teachers are preparing them to teach all three sciences to pupils aged up to 16 years.
- the minimum degree classification requirement Higher Education Institution tutors expect for a biological science pre-service teacher is higher than for a physical science pre-service teacher teacher.
- Nearly one third of pre-service teachers who categorise themselves as physicists have a degree with minimal or no physics content.

One year Initial Teacher Training courses do not equip newly qualified teachers to teach all sciences to pupils aged up to 16 years. There is a need to raise awareness for policy makers and senior managers in schools that continuing support for subject knowledge and topic specific pedagogy is needed for newly qualified teachers and that this support should continue into the early years of their careers.

In view of the varied practice in addressing subject knowledge and topic specific pedagogy there is a need for university tutors engaged in Initial Teacher Training to share practice. However, opportunities for sharing practice have declined due the demise in 2010 of support from both the Regional Science Consortium meetings and the National Strategy Science Team. This gap could be filled by the Association for Tutors in Science Education, through the Association for Science Education, by extending their role to facilitate the sharing of practice through their journals, annual research conference and website.

USING SLOWMATION TO MAKE SCIENCE PRE-SERVICE TEACHERS` BELIEFS EXPLICIT

Silvija Markic[1], Stephen Keast[2] and Rebecca Cooper[2]
[1]University of Bremen, Germany
[2]Monash University, Melbourne, Australia

Abstract: Universities in Bremen (Germany) and Melbourne (Australia) researched the use of Slowmation in their pre-service science teacher education courses to investigate its effectiveness in making pre-service teachers' beliefs explicit. In Germany, pre-service teachers in a chemistry course made Slowmation movies of their beliefs of effective teaching of chemistry. They presented their Slowmation movies to their peers and discussed the similarities and differences in the beliefs they saw. In Australia, pre-service teachers learnt Slowmation and used it on their teaching practicum with their pupils. On their return to university the pre-service teachers showed their Slowmation movies to their peers and discussed their teaching of it. Data was collected by video-recording the presentations and discussions, and using questionnaires. In both countries Slowmation proved effective in engaging pre-service teachers in discussions of their beliefs of science teaching and learning. Identifying pre-service science teachers' beliefs should be an important part of science education courses and Slowmation had proved a useful teaching procedure that makes explicit pre-service teachers' beliefs of what constitutes effective science teaching.

Keywords: Pre-service teachers' beliefs, teacher education, Slowmation

THEORETICAL BACKGROUND

Research in science education has been focusing on students' and teachers' beliefs for many decades. Such research began with researchers investigating the different beliefs related to specific scientific content, such as Bandura (1986) who found that beliefs tend to be the best indicator of one's personal behaviour. Expanding on this idea, Pajares' (1992) reported that beliefs played a crucial role in not only defining personal behaviour, but also in the way a person organized their knowledge and information. Taking this one step further, we can assume that pre-service teachers' beliefs affect both their learning and their understanding of teaching throughout their teacher education program (Fischler, 2000). On the other hand, pre-service teachers also have to be prepared to understand and know about their pupils' beliefs about a multitude of scientific topics. However, at university it is not possible to study all possible alternative conceptions pupils may have about each and every scientific topic. In our science education courses we have been searching for ways to make pre-service teachers' beliefs explicit, have them reflect on these and then build into the course ways that will have them reconsider their beliefs about what is effective teaching and learning in science. Dewey (1933) stated: "Reflection is an active, persistent, and careful consideration of any belief or supposed form of knowledge in light of the grounds supporting it and future conclusions to which it tends" (p. 6). This research examines whether Slowmation as a new teaching procedure can be effective in making explicit the pre-service teachers beliefs of science and the teaching and learning of science across two countries.

Slowmation is a 'Teaching Procedure' (Mitchell, 2007) based on elements of clay animation designed to engage students in constructing ways of demonstrating their understanding of science concepts and science ideas. In contrast to clay animation where clay or plasticine figures are photographed and shown quickly to simulate continuous 'near life' movement, Slowmation uses a variety of materials and is played at 2 frames per second to produce "slow animations" (hence the term Slowmation). In this study, the Slowmation process was introduced to preservice secondary science teachers who made short movies about abstract science concepts. The purpose of using Slowmations in this way with preservice science teachers was in order to explore their understanding of science concepts. In so doing, it was anticipated that they might see the value in using the procedure with their students when they were teaching (on their practicum) and therefore gather insights into their students' understanding of science concepts (see Keast, Cooper, & Bullard, 2011 for discussion of one such case).

Slowmation has been pioneered by Hoban (Hoban, 2007; Hoban & Ferry, 2006; Hoban, McDonald, & Ferry, 2009) at the University of Wollongong through extensive work with Primary pre-service teachers over several years with a major goal of producing useful classroom resources in science. The Slowmation process has proven to be remarkably successful in engaging pre-service teachers with some participants spending upwards of 20 hours outside of scheduled class time to produce movies to be shared through an online forum. Hoban's work led to a successful Australian Research Council (ARC) Discovery Project (Hoban, et al., 2008) spanning three universities (Wollongong University, Monash University and University of British Columbia) and two continents (Australia and Canada).

RATIONAL

Slowmation (Hoban, 2005, 2007) is not a software package, rather it is a 'Teaching Procedure' (Mitchell, 2007) based on elements of clay animation designed to engage preservice teachers and pupils in ways of demonstrating their understanding of concepts and ideas by creating simple animated movies. In contrast to clay animation where clay or plasticine figures are photographed and shown quickly to simulate continuous 'near life' movement, Slowmation uses a variety of materials and is played at 2 frames per second to produce "slow animations" (hence the term Slowmation). Our paper presents two different uses of Slowmation in science teacher education. The data was collected in two countries: Germany and Australia and while both countries differ in their teacher education system this paper demonstrates how Slowmation can be used in very different contexts.

The research questions guiding this research were:

> *Can Slowmation be effective in making explicit the pre-service teachers` beliefs of science and teaching science across in Germany and Australia?*
>
> *How do pre-service teachers react to utilising Slowmation as a part of their teacher training?*

SAMPLE AND METHOD

In Germany, chemistry pre-service teachers developed Slowmation movies as a part of their seminar "*Diagnosis and Planning of Chemistry Lessons*". Slowmation was used to make chemistry pre-service teachers' beliefs about chemistry teaching and learning explicit for them. There were 21 German chemistry pre-service teachers who took apart in this study, and they were in the fifth semester of their course and were preparing for a one month school internship. The pre-service teachers are almost at the end of their Bachelor Degree and have completed 60 hours university practicum in secondary schools for one other subject (mainly biology). One of the aims of the present seminar is to make pre-service teachers` beliefs about teaching and learning explicit so that can reflect on them. Starting from this aim, pre-service teachers had the opportunity to become acquainted with the method of Slowmation and to reflect upon its use as a teaching procedure in their chemistry classes. They made their movies about their ideal chemistry lesson in groups of two, with time at home over one week to finalize production and presented them in class at the next tutorial. After the Slowmation movies had been presented, the pre-service teaches discussed the similarities and differences in the beliefs presented in the each Slowmation movie. The data was collected from a qualitative perspective by the first author during this class. The first set of data collected was the observation of the pre-service teachers and consisted of detailed field notes made during the first seminar session while pre-service teachers were planning their Slowmation. The second data set was collected comments from pre-service teachers when they presented their Slowmation to the class. The third and final data set from Germany consisted of collecting pre-service teacher responses to an open ended questionnaire.

In Australia, 24 preservice teachers developed Slowmation movies as part of their course work, and introduced Slowmation into their science classrooms during their school practicum. On their return to university following this practicum the pre-service teachers presented the Slowmations created by their students to their colleagues and lecturers, and discussed the impact of introducing this procedure on their students' learning about science concepts. In Australia, the research also took a qualitative approach and data was collected by video recording the presentations and analysing them for themes. (for more detail of this ongoing research see Keast, Cooper, Berry, Loughran, & Hoban, 2008; Keast, Cooper, Berry, Loughran, & Hoban, 2009; Keast, Cooper, & Hoban, 2010a, 2010b). The purpose of using Slowmations in this way with pre-service science teachers was for them to explore their beliefs and understanding of teaching and learning science. In so doing, their discussions of their teaching Slowmation in school covered many of the big ideas outlined in the Australian course which the authors believe built on their growing understanding of their pedagogical context knowledge (Morine-Dershimer & Kent, 1999).

In both contexts and in the two countries, the authors focus on their pre-service teachers' reflections on their beliefs of science and teaching and learning science through the use of Slowmation, rather than focusing on the technical usage of Slowmation or producing polished finished product. In this way Slowmation was a catalyst for generating reflection and discussion of the pre-service teachers' beliefs about teaching and learning science.

RESULTS AND DISCUSSION

Germany:

Slowmation was a new teaching procedure for the German chemistry pre-service teachers. However, they were open to the use of this new procedure and could see benefit in its use for their teaching. From the beginning, it was easy to see that chemistry pre-service teachers like the method of Slowmation and see it as a hands-on, innovative and novel procedure compared to the other education courses and seminars they had been involved into this point.

During the making of the Slowmations, it was interesting to see the discussion between the group members that developed one movie. Already the participants noticed that they had different beliefs about what constituted an effective chemistry class and needed to negotiate what aspects were to be included. They started their discussions from the position of the teacher in the classroom, moved on to the role and craft of experiments (from both the teacher and student perspectives), and then discussed more detailed issues of teaching and learning. In some cases they discussed the role of the media (TV and Laptop) in the chemistry classroom and importance of how it is best to use such technologies. However, the topic was that each group should make one Slowmation of effective chemistry teaching. To do so, the participants of each group needed to agree to one example of teaching and it was during these discussions that the pre-service teachers began to explain to each other their own beliefs. Such discussions brought considerable argument and justification for having such beliefs and led to in-depth explanation of the individuals' position. On the one side pre-service teachers were arguing from educational perspectives (constructivism, scientific literacy) to explain their beliefs about how an effective chemistry classroom should be presented. On the other side, one pre-service teacher spoke of his experience in classes and the need to be more pragmatic. This pre-service teacher was older than his peers and had 2 years experience working as a chemist in a German chemical company. After he started as a chemistry teacher in the lower secondary level, he decided he needed a chemistry teacher training program to improve his understanding of the educational theories he thought he was lacking. However, he was very different in his beliefs which were so dominantly influenced by his teaching experience. He repeated often:

> *Yes, that is what is written in a book. But, believe me; the kids are not like in a book. So you cannot be like that and must handle it differently. (Student T, Germany)*
>
> Or
>
> *That would never work in my class. You have to have the control in your classroom. That is also what my colleagues say. (Student T, Germany)*

This pre-service teacher was very resistant to change his beliefs about effective chemistry teaching and the ideal chemistry classroom. Other pre-service teachers in this group, and other groups were more open for reconsidering their beliefs in light of the position and arguments of other group members. Finally his group made a Slowmation that was a compromise of the range of different beliefs the group had. Presenting their Slowmations, the pre-service teachers were surprised with the range of different beliefs about effective teaching that were presented by their class peers. The pre-service teachers in this study were paying attention mainly to the role of the teacher in the classroom, the student-activities and the role of experiments in the presented scenarios. One revelation came from a pre-service teacher in regards to position of the teacher in the room and the implications of student centred versus teacher centred teaching:

> *In all of the movies I was paying attention to a teacher. It was so funny to see in the last movie, that the teacher was all the time somewhere at the side. In one moment I was thinking "he is doing nothing!". In my movie, me as a teacher was doing something, I was having contact to my students all the time. I was in the middle of the classroom. From this I realised I liked to be in control and didn't run a student-centred classroom. (Student K, Germany)*

The response showed that the preservice teacher needed to be in the middle of the learning, they did not believe that effective teaching would allow the students to be the centre of their own learning. The questionnaire showed that the pre-service teachers saw Slowmation as an effective method for making their beliefs explicit and a helpful approach for discussing the alternative views about teaching and learning. The chemistry pre-service teachers in this study see Slowmation as a new, innovative and creative procedure for their teacher education course. They thought the preparation of the Slowmation was a long process (especially for those who were not familiar with the computer program Windows MovieMaker). However, they were willing to make the movies again and see the future use of Slowmation as effective in their chemistry classes.

Australia:

The classroom presentations and discussions of school students' Slowmation movies post practicum provided valuable feedback to the preservice teachers about their beliefs about teaching and their students' learning.

> *Slowmation includes a good learning situation for my students because they had to translate the material from 2D (dimensional) (the pictures in the text book) to 3D (models for the movie). But also when they are deciding what to do, they are discriminating between what is important to show in the movie and what is not. And that to me is the real learning. (Student J, Australia)*

In this comment the preservice teacher articulates what she believes is the real learning in her classroom. For her Slowmation created opportunities between her students in their individual groups to discuss what was important in the science process and how they understood the science. Learning also occurred as students translated information from the text and 2D diagrams into 3D models and then animated these. Mitchell (2007) describes such work as translation tasks, "Students are asked to translate a piece of information from one form into another. The process helps students to actively process what they know and to identify what they don't know. Because this task can be tackled in many ways, it provides an opportunity for student choice and independent decision-making …" (p.15). Slowmation allows students the choice of how they represent the science concept and in animating it they start to understand the process as they move between stages.

Another preservice teacher commented:

> *These students were never asked to consider themselves as learners or to recognize their own learning. I feel this is very important. (Student M, Australia)*

Making learning explicit and helping students recognise when they were learning and how they were learning was a belief about science learning that was revealed by this student during her presentation. The Slowmation presentations allowed preservice teachers to share their classroom experiences through the artefacts that replayed the students understanding. In this way the preservice teachers discussed issues of learning that are otherwise difficult to explicate in the classroom.

Another preservice teacher was concerned with teaching science systems as isolated rather than as belonging to a larger interconnected system:

> *Students should probably show how systems interact and make those links between systems; like the students doing the digestive system [here] should show how that system is impacted by other systems. They shouldn't be taught in isolation. (Student A, Australia)*

In each of these examples the Australian students have not only recognised important features of science learning, but they have also articulated publicly and with conviction their beliefs about what constitutes effective learning in their science classrooms.

CONCLUSIONS AND IMPLICATIONS

From different studies we know that pre-service teachers' beliefs can be influenced and developed during the teacher education program (eg. Markic & Eilks, 2010). It is clear from the present study that Slowmation was an effective teaching procedure to make explicit pre-service teachers' beliefs about science and teaching and learning science. Not only did pre-service teachers get to know new methods for reflection and self-reflection, they were also motivated to do so and enjoyed doing it. Seeing their colleagues' alternative beliefs led these pre-service teachers to think carefully about their own beliefs in light of the thinking of their peers. Pre-service teachers were given the opportunity in each country to discuss their own beliefs with their colleagues, think about their own beliefs and compare them with those of their peers. The authors see pre-service teachers making their beliefs public as the first step in the process of changing beliefs. Teaching procedures such as Slowmation should be incorporated more often in university teacher education programs to make explicit the beliefs of pre-service teachers. Furthermore, the knowledge and insights into pre-service teachers' beliefs can help science educators to better understand their students and the beliefs they bring about teaching and learning to their units. This allows teacher educators to plan their lecturers and tutorials in ways that challenge and hopefully in time change such beliefs. Finally, the authors believe that the adoption of Slowmation has been useful in both Germany and Australia to make explicit pre-service teachers' beliefs and should be considered as an effective procedure to be used by other teacher education programs.

In the Australian context, Keast and Cooper started using Slowmation to make explicit pre-service teachers` beliefs and their research has developed into pre-service teachers using such beliefs to situate their 'Pedagogical Knowledge' (Morine-Dershimer & Kent, 1999). Keast and Cooper's learning as both as researchers and teacher educators had been influenced by the knowledge they have constructed of their practice and that of their pre-service teachers understanding of teaching science by using Slowmation. As they look at Markic's work here, they look back at where they were several years before. Through reflection on their research, their practice of teaching with Slowmation has changed to elicit more from their students about their understanding of science teaching. As Dinkelman et al. (2006) suggest, "developing an identity and a set of successful practices in teacher education is best understood as a process of becoming" (p.6). Keast, Cooper and Markic believe that Slowmation can be a useful tool to improve and advance this "process of becoming" for those science teacher educators who use it in a purposeful way to reflect on their own practice and understandings of teaching about teaching science.

COMPARISON OF GERMAN AND MALAYSIAN PRE-SERVICE SCIENCE TEACHERS BELIEFS` ABOUT TEACHING AND LEARNING

S*ilvija Markic*[1]*, Maryam Sulaiman*[2]*, and Zurida Haji Ismail*[2]
[1] University of Bremen, Germany
[2] Universiti Sains Malaysia, Malaysia

Abstract: Research on teachers` beliefs is considered to be more important in science education. Teachers` beliefs constantly influence their acting in the classroom. It can be assumed that the beliefs pre-service teachers hold in prior to their training and while taking courses will influence their understanding of how to teach during their training program. Research in this area has focused either on (i) one specific group of pre-service teachers or (ii) one specific aspect of the pre-service teachers' beliefs. Furthermore, most studies are applied within one country, with respect to one educational and cultural background. The study aims to compare data from Malaysian and German pre-service teachers who are at a comparable stage of their teacher training. The same questionnaire was administered to pre-service teachers in both countries. The questionnaire required the pre-service teachers to draw themselves and their students in a typical science classroom situation. Data was analyzed based on Grounded Theory to offer holistic insights into the beliefs about teaching and learning. Data shows that the pre-service science teachers in both countries hold quite modern beliefs about teaching and learning. Furthermore, while the German group seems to be more homogeneous about their beliefs, the group from Malaysia is more heterogeneous. The cultural influences and implication for the science teacher education for both countries will be discussed.

Keywords: pre-service teachers`s beliefs, Germany, Malaysia, teacher education

FRAMEWORK AND OBJECTIVES

Beliefs play an important role in how teachers organize knowledge and information and are essential in helping teachers adapt, understand, and make sense of themselves and their world (Schommer, 1990). How and what teachers believe have a tremendous impact on their behavior in the classroom (Pajares, 1992; Richardson, 1996). As teachers` beliefs connects to teacher's practices (Richardson, 1996), therefore, the belief teachers hold should influence their classroom judgments and actions. Hence, better understanding about teachers` beliefs is essential to improve teaching practices (Pajares, 1992; Richardson, 1996) since teacher's belief provides a true window to look at their decision making and instructional practices (Nespor, 1987; Pajares, 1992). Teachers` beliefs influence how teachers' present science in their classrooms and the kinds of opportunities they provide for students to learn science (Roth et al., 2006). Therefore, research on teachers' beliefs has been considered as essential in science education. The pre-service teachers` beliefs which are deeply held, and often unexamined, need to be sought out by teacher educators to provide pre-service science teacher with ample opportunities to develop a teaching and learning science classroom that are aligned with current reforms. The pre-service science teachers' beliefs need to be developed into the direction that science should be taught accordingly within the recent context. Fenstermacher (1979) argued that one goal of teacher education is to help young teachers transform tacit or unexamined beliefs about teaching, learning and the curriculum into objectively reasonable or evidentiary beliefs.

Markic and Eilks (2010) analyzed the beliefs of 85 German chemistry pre-service teachers about chemistry teaching and learning at the beginning of their teacher education. The majority of chemistry pre-service teachers from this sample showed teacher-centered beliefs. In contrast, the modern theories of learning and instruction are based on a framework of constructivism which calls for student-centered teaching approaches. Tanase and Wang (2010) study the transformation of initial epistemological beliefs of four pre-service teachers on one teacher education classroom course. Study suggests that participants' epistemological beliefs about learning could affect their teaching and the transformation of their beliefs could also lead to the change of their teaching ideas and practice. Also, a conceptual change of pre-service teachers is only possible through a long-term process. Yilmaz-Tuzun (2008) examines the 166 pre-service elementary teachers' beliefs about science teaching from three Midwestern universities. In this study, he explored the pre-service elementary science teachers' beliefs regarding self-reported comfort level about their abilities to apply traditional and reform-based teaching methods, utilize assessment strategies and classroom management techniques, and teach science content. It was assumed that pre-service teachers' belief systems and the knowledge they gained through methods courses are in relation with their further teaching experiences.

This study stems from different educational backgrounds and educational systems. Furthermore, the political system, culture and the state religion are also in most of the cases not comparable. On the other hand, the instruments used in the different countries are not the same and focus on different beliefs and beliefs systems. However, most of the studies in this research area are focused either on (i) one specific group of pre-service teachers or (ii) one specific aspect of the pre-service teachers' beliefs. The present study adopts the instrument and evaluation pattern presented in Markic and Eilks (2010) to look into the pre-service science teachers` beliefs from different educational and cultural backgrounds. The study compares data from Malaysia and Germany`s pre-service teachers which are at a comparable stage of their teacher training. The general research questions of the present paper are:

(1) What general conclusions can be drawn about the beliefs of science/chemistry pre-service teachers in Malaysia and Germany?
(2) Are there any differences in beliefs that Malaysian and German science/chemistry pre-service teachers hold about teaching and learning?

METHOD AND SAMPLE

In this qualitative case study, participants were instructed to draw themselves as science teachers in a typical classroom setting found in their chosen subject and to answer four open questions. This idea relates to the 'Draw-A-Science-Teacher-Test Checklist' (DASTT-C) (Thomas, Pedersen & Finson, 2001), supplemented with questions about teaching objectives and previous activities. Development of the data analysis pattern occurred using Grounded Theory (GT) as described in Markic, Eilks and Valanides (2008). The core category based on GT is the range between the predominance of more traditional versus more modern teaching orientation in line with educational theory. Three 5-step scales were developed with a GT focus on 1) *Beliefs about Classroom Organization*, 2) *Beliefs about Teaching Objectives* and 3) *Epistemological Beliefs*. The validity of the data was achieved through independent rating and searching for inter-subjective agreement (Swanborn, 1996). The evaluation pattern developed using GT does not present a linear scale. The numbers are only the symbols for the descriptions that are made along the data. The short description of the three categories is presented in Table 1. More detailed information can be found in Markic et al. (2008).

	Traditional view		**Modern view**
Belief about Classroom Organization	The classroom activities are mostly teacher-centered, directed, controlled and dominated by the teacher.	↔ -2, -1, 0, 1, 2	Classes are dominated by students' activity and students are able to choose and control their activities.
Belief about Teaching Objectives	The focus of science teaching is more or less exclusively focused on content learning.	↔ -2, -1, 0, 1, 2	Learning of competencies, problem solving or thinking in relevant contexts are the main focus of teaching.
Epistemological Beliefs	Learning is passive, directed and controlled by dissemination of knowledge.	↔ -2, -1, 0, 1, 2	Learning is a constructivist, autonomous and self-directed activity.

Table 1: An overview of the three scales

The sample of the present study contains Malaysian and German group of science/chemistry pre-service teachers which are at the comparable stage of their teacher education program.

<u>*Malaysia*: </u>The sample consisted of 43 pre-service teachers from Universiti Sains Malaysia. Subjects were third year of Science Education Degree Program enrolled in the chemistry teaching methods course. The course is compulsory for students who chose chemistry as their major/minor subject. The course focuses on delivering instructional strategies and educational theories that form the framework for teaching and learning chemistry. The course was conducted for one semester consisting of 14-weeks.

<u>*Germany:* </u>The German group of pre-service teachers (N=31) was halfway through their 5-year university education program. This group had already had several chemistry lecturers and seminars, including some education and science education courses. The participants had just returned from a half-year teaching internship in school. The pre-service teaches are mostly between 21 and 25 years old and there is a balance between male and female in this group. A majority of pre-service teachers are coming from the North part of Germany and got their requirement for university administration at German grammar school.

However, in both cases, the selection of this data sample was not representative in a statistical sense. Nevertheless, most of the Malaysian and German pre-service teachers possess similar formal qualifications for access to university study. The age and gender distributions were very prototypical for similar groups of pre-service teachers in the respective subjects. Using this point-of-view as a springboard, there is no sound reason to assume that these pre-service teachers are uncommon in any respect. There can be no obvious assumption that the results would differ significantly by sampling a new test group from other German universities involved in science teacher education. Through selection of the sample, this case study remains valid as to its source of information, allowing careful analysis of pre-service teachers' beliefs in the sciences all over Germany.

RESULTS AND DISCUSSION

All three categories were interpreted as representing a range between more traditional and more modern beliefs with regards to educational theory and research evidence (see Markic & Eilks, 2008).

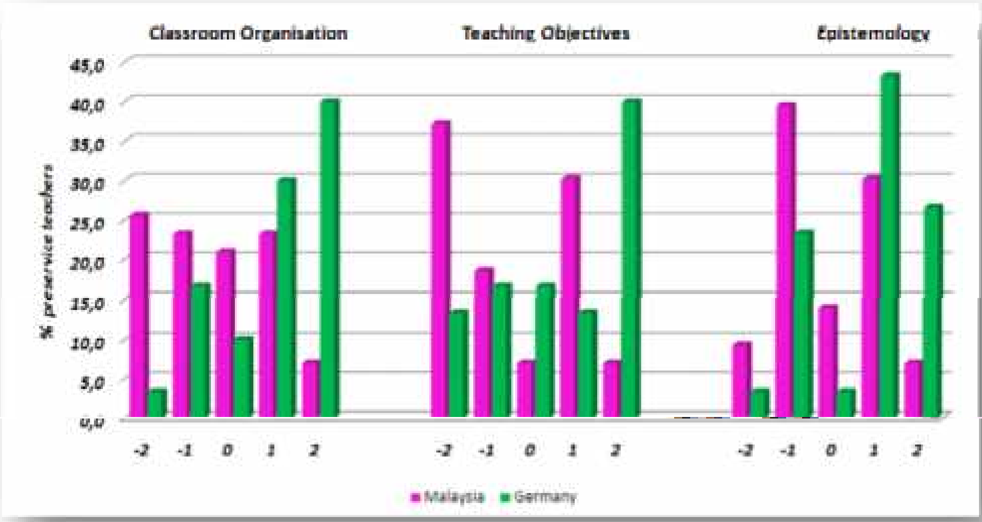

Figure 1: Visualization of the percentages for the three categories

The results in Figure 1 represent a broad diversity of beliefs within the group as a whole, but also show contrasts within the respective pre-service teachers from Malaysia and Germany.

The Malaysian pre-service science teachers tend to hold more teacher-centered beliefs when it comes to teaching and learning science. Concerning *Beliefs about Classroom Organization* this group seems to be most heterogeneous, though there is a slight tendency to teacher-centered classroom organization. The data presented for *Beliefs about Teaching Objective* is heterogeneous but not as the first category. Roughly 60% of this group illustrates that teaching science is preferred to be exclusively content-structure focused; with learning content is the central objective. Finally, for the *Epistemological Beliefs* Malaysian pre-service science teachers` beliefs are in balance. All pre-service science teachers show highest numbers at code -1 and high at code +1, other codes show low frequency. Code -1 illustrates that learning science is even though over-directed with student-active phases but still follows a storyboard written by the teacher. Learning though conducted by the students but still organized and directed by the teacher.

The German chemistry pre-service teachers tended to hold more modern beliefs when it comes to chemistry teaching and learning. Furthermore, this group of pre-service chemistry teachers seems to be more homogeneous in their beliefs about chemistry teaching and learning. The analysis of German group shows heterogeneous allocations for all three categories, but especially for *Beliefs about Teaching Objectives.* Those beliefs are describing the knowledge of competencies and problem solving as a main focus of teaching. Additionally, students` thinking in relevant contexts and other affective outcomes are the main objectives of the lesson. Furthermore, in the other two categories, this group leaned quite strongly towards student-centered. German chemistry pre-service teachers bring more modern teaching and learning at this stage of their teacher education program. These beliefs are characterized by student-centered classroom organization and constructivist learning.

Another important aspect of the data is related to interpreting the data combinations found among the three categories. If a pre-service teacher shows similar classifications in each of the three categories, then the combination of codes will appear along or near the diagonal line from (-2/-2/-2) to (2/2/2) in 3D-diagram. The code combinations for the both countries are represented in Figure 2.

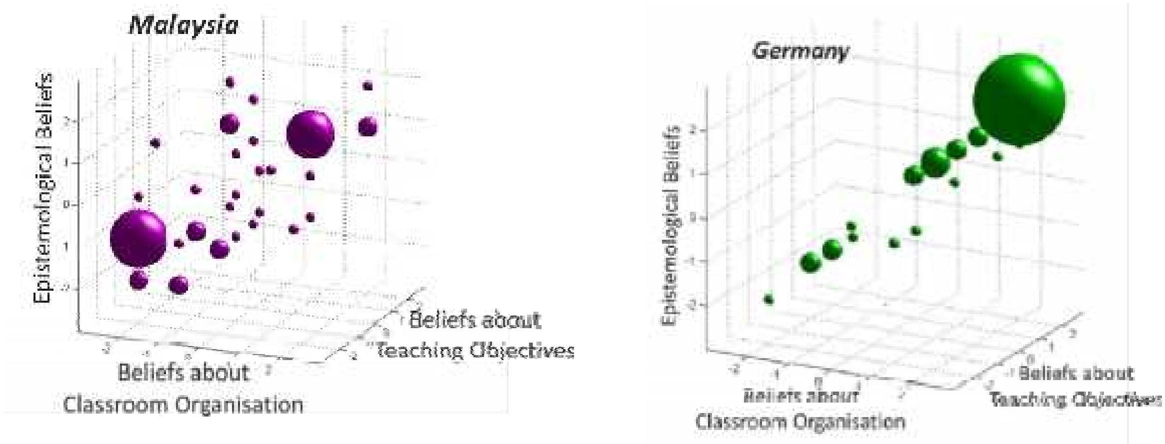

Figure 2: 3D-representation of the code combinations for both countries

Figure 2 shows a high proportion of pre-service teachers' code combinations for both countries occurring near the spatial diagonal. This means that the beliefs tested are interdependent upon one other (see also Markic & Eilks, 2008). Furthermore, the closer a pre-service teacher's code combination approaches the lower, left, front most portion of the three-dimensional plot, the more traditional the pre-service teacher's beliefs about teaching and learning will be. The nearer a code combination approaches the upper, right, hindmost corner of the diagram, the more the pre-service teacher's beliefs fall in line with modern educational theory.

Malaysian pre-service science teachers tend to hold a broad diversity of beliefs about science teaching and learning. A very large number of the collected data in Malaysian group appears in the lower, left, frontal part of the diagram. However, almost the same number of pre-service teachers` code combinations in this group is anywhere near the upper, right, back part of the diagram. Contrary to this result, German chemistry pre-service teachers are more homogeneous in their beliefs about teaching and learning of chemistry in the middle of their teacher education program. Most of the pre-service teachers in German group show results which are located in the upper, right, back part of the diagram. This indicates beliefs remaining more in line with modern educational theories. This group favors by the majority student-centered approaches, including ideas stemming from constructivist learning, and an orientation towards scientific literacy objectives.

CONCLUSION AND IMPLICATION

There are noticeable differences between the two groups of pre-service science teachers studied. Whereas German pre-service teachers are more homogeneous (with the group tending towards modern educational ideas), Malaysian teacher trainees show a much more diverse range of diverging beliefs, which are widely scattered between traditional and modern ideas about teaching and learning in Science. It would seem that many pre-service teachers in Malaysia do not hold beliefs consistent with modern educational theories and methodologies.

There are differences between the two groups of science/chemistry pre-service teachers to see. While the German pre-service teachers are more homogeneous as a group and hold more modern beliefs about teaching and learning of chemistry, Malaysian pre-service teachers groups is at the comparable stage more heterogeneous showing traditional and modern beliefs about teaching and learning as well. Here we can say that it seems that in Malaysia not all of the pre-service teachers see themselves teaching in line with modern educational theories. In Germany the development and modern/student-centered beliefs are one part of the university teacher education program, not only in courses and seminars, but also in teaching internship at school. At this point, it is to say, that this study should be an impulse for thinking about changes in science teacher education program in Malaysia. It seems that the seminars and courses in Malaysia are not sufficient in line with modern teaching and learning theories. It is to think about how the (potential) developed traditional beliefs during the own time as a pre-service teacher should be reflected, changed and developed. Thus, university seminars and lecturers are needed, who base their efforts on modern research theories and discuss theoretical aspects of their fields, can and do influence pre-service teachers` belief system in a more modern attitude.

From other studies we know that German pre-service teachers generally have more traditional beliefs at the beginning of their tertiary education (Markic & Eilks, 2008), but that those beliefs can be altered during the course of the teacher education program (Markic & Eilks, 2010). Starting there, one possible explanation for the differences in results among German and Malaysian teacher trainees might be explained by the different teacher education programs in both countries. It seems likely that education programs geared towards higher levels of pedagogy and science education from the first semester onward - as is the case in Germany - can influence pre-service teachers' beliefs about education in a more modern attitude. One question which immediately arises is whether Malaysia might also reap similar rewards by including a focus on such coursework in the early phase of teacher trainee educational programs. This might allow Malaysian teacher trainers to instigate an early, sustainable change in their pre-service teachers` beliefs about teaching and learning. Further research will be required to investigate this aspect.

THE COGNITIVE AND LINGUISTIC SKILLS ASSOCIATED TO HUMAN NUTRITION IN TEACHER TRAINING

Cristina Martínez-Losada[1], *Susana García-Barros*[1] *& Rut Jiménez-Liso*[2]

[1]A Coruña University - Spain -

[2]Almería University - Spain -

Abstract: The aim of this study is to find out the importance that trainee Primary and Secondary teachers give to the evaluation of certain cognitive and linguistic skills in relation to certain key ideas associated to human nutrition and to what extent they identify these skills in the evaluation questions asked. 270 questions were analyzed, proposed by 54 groups of teachers during a training activity included in the theme of evaluation. The educational importance of the use and development of these aforementioned skills were previously dealt with. The results show that the future teachers give more importance to the description and definition than to the justification. Moreover, differences can be seen depending on the key idea being considered and, at times, depending on the group of teachers. It can also be seen that the teachers are not always aware of the skill they require in their questions. This shows that attention should be given to this area in teacher training as justification is essential for the understanding of the subject of human nutrition, in Primary as well as in Secondary.

Keywords: Cognitive and linguistic skills. Human nutrition. Teacher training. Primary. Secondary.

INTRODUCTION

In recent years the importance of language in scientific learning has become clearer, in how it allows ideas to be expressed and organized (Rivard & Straw, 2000; Jiménez Aleixandre, 2003; Prain, 2006). An important objective of scientific education is for students to be able to give scientific explanations. In coherence with scientific discourse, students have to use the language in an interpretive manner (Sutton, 2003), taking a certain theoretical framework as a reference. This requires the use of cognitive and linguistic skills that have different levels of difficulty (Jorba *et al* 2000). Amongst these are included: a) the description of facts and processes, "how it is, what's happening"; b) the definition of a concept, necessary for identifying it, "what it is" and c) the justification of the facts/processes, "why it is, why it is happening".

It would be desirable for teaching to promote the use of the aforementioned skills in relation with specific contents, with the questions being asked in the classroom being a key element in their development. However, the activities included in Spanish textbooks for the study of human nutrition usually focus more on the anatomical and functional descriptions of the systems involved or on the description of the different types of food, but little attention is paid to the justification of the function itself or to the importance of a particular diet (García Barros & Martínez Losada, 2005). Teacher training constitutes one of the most ideal systems for overcoming these problems. Such training should take into account the cognitive and linguistic skills involved in scientific learning, as well as the thinking of the trainee teacher with regards to these, with the aim of promoting their professional development (Hewson *et al*., 1999).

This study aims to find out: a) which skills the trainee teachers of Primary and Secondary consider to be important in relation to specific contents of human nutrition and b) to what extent these teachers identify these skills in the questions asked.

METHODOLOGY

270 evaluation questions have been analyzed, proposed by 54 groups of trainee teachers (32 groups from Primary education and 22 from Secondary education). Each group was made up of two students.

The questions were written in the context of an initial training course for Science teachers and, more specifically, during a training activity included in the theme of evaluation. In a previous subject we presented and discussed the educational value of cognitive and linguistic skills required by the questions which are asked in the classroom. Each group had to propose five questions directed at evaluating the learning, achieved by some hypothetical Primary and/or Secondary students, relating to four key ideas, associated with nutrition in humans and that had supposedly been dealt with previously in the class: a) Human nutrition – nutrition as a vital function; b) Implicated systems – anatomy, function and specific processes of each system; c) Food – types and functions of food/nutrients; d) Food and health – characteristics and the importance of healthy eating. They were also advised that they had to decide the degree of difficulty of the questions and they were reminded of the possibility of requesting a description, definition or justification.

The questions contributed by the teachers were grouped both according to the skill it requires (description, definition or justification) and according to the key idea it dealt with (human nutrition, implicated systems, food or food and health).

FINDINGS

All the groups of Primary and Secondary trainee teachers asked at least one question that required a description and around 90% of each group asked some question that required a definition (Figure 1). Practically all of the Secondary groups asked at least one question that required a justification. Only 47% of the Primary groups asked for this skill.

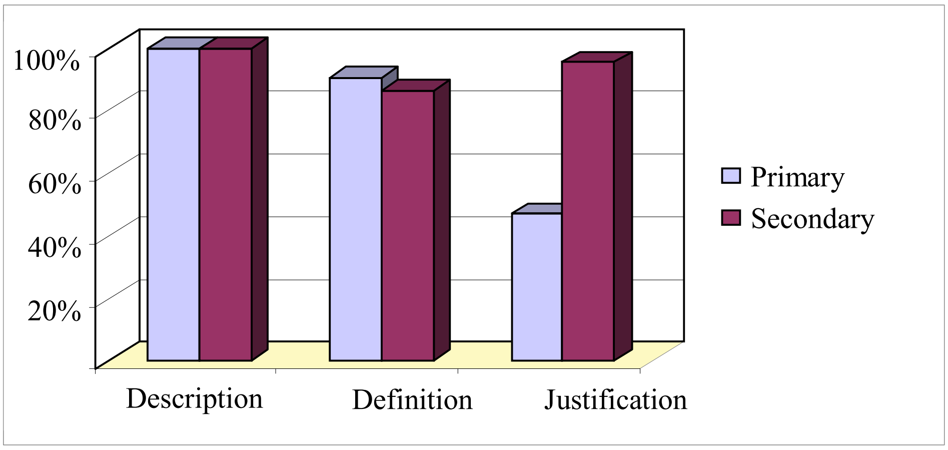

Figure 1: Percentage of groups that required various skills in the evaluation questions.

The skill required in the questions varied in terms of the key idea considered and also, at times, depending on the group of teachers. In table 1 the number of groups is included that asked for a certain skill in relation to each key idea, as well as an example representative of the type of questions asked. In particular, it could be seen that:

- With respect to nutrition the most requested skills in the two groups is definition, while with respect to the systems involved the most requested skills was description.
- With respect to food and to the food/health relation, description is always the most requested skills in the Primary group. However, in the Secondary group the most requested skill is definition (in the case of food) and justification (in the case of food and health).

Key ideas/Associated skills		**Primary** N= 32	**Secondary** N= 22	**Examples of questions**
N. Human nutrition	**N-Ds.** Description of the process	10 31.3%	8 36.4%	• *"Complete…: Human beings need... the foods in… , that they use for…*
	N-Df. Definition of nutrition	**26** **81.3%**	11 50.0%	• *"What is nutrition?"*
	N-J. Justification of its function	12 37.5%	8 36.4%	• *Why do we say that nutrition is a vital function?*
S. Systems involved	**S-Ds.** Anatomical/ functional description	**31** **96.9%**	**19** **86.4 %**	• *Name the following organs and equipment in the illustrations* •
	S-Df. Definition of its function	1 3.1%	2 9.1%	• *What systems are involved… and what function does each one serve?*
	S-J. Justification of its function	--	4 18.2%	• *What do you think would happen of the circulation system didn't exist?*
A. Food	**A-Ds.** Description of types of food	**20** **62.5%**	8 36.4%	• *Classify the following foods in terms of their origin. Indicate which nutrients each food has.*
	A-Df Definition of the food/nutrient	16 50.0%	15 **68.2%**	• *What are foods? What are nutrients?*

Ds, description; Df, definition; J, Justification

Table 1. Percentage of groups that require different skills in evaluation questions, associated to each key idea

The Trainee teachers do not always identify which skill is required from the questions asked (Figure 2). Less than 60% of the groups from both Primary and Secondary that asked for a description, in terms of the various key ideas, recognize this request. However, the percentage is higher in the case of the justifications and even more so in definitions.

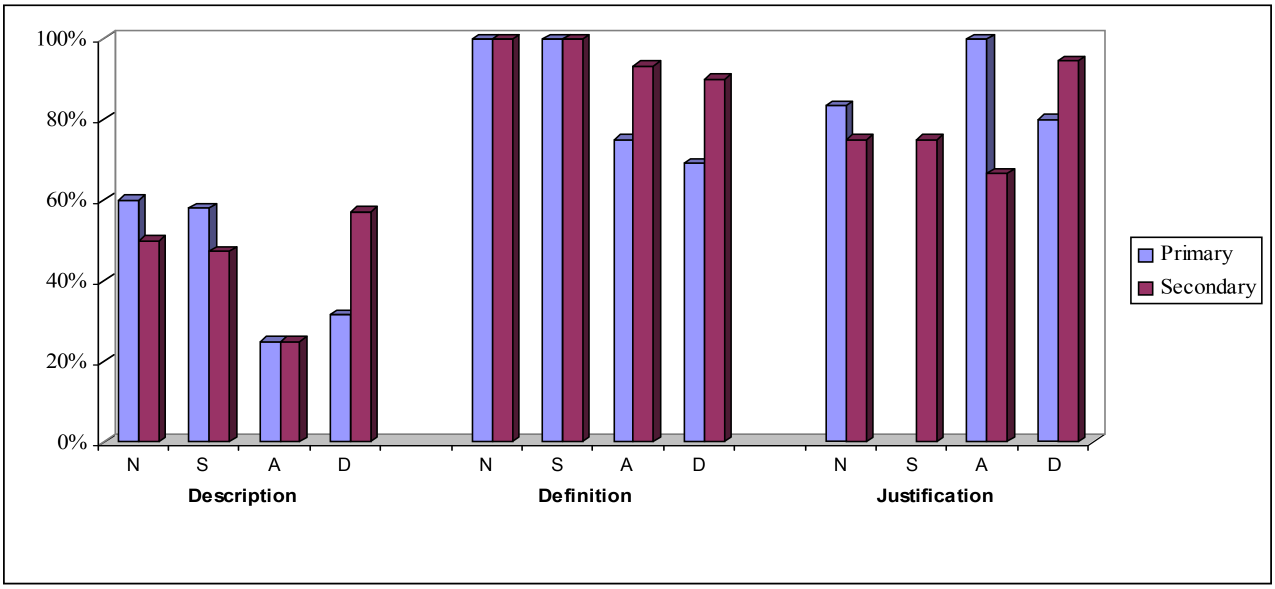

Figure 2. Percentage of groups that identify the skills requested in the evaluation questions.

Now let us look further into the type of skill which the teachers identify in the descriptive questions asked. The majority of the groups which did not recognize that they are asking for a description believe that they are asking for a justification (Figure 3).

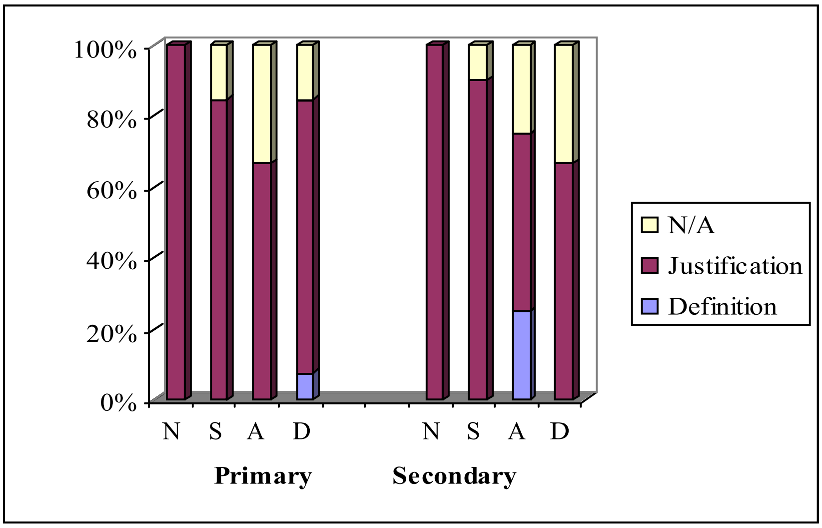

Figure 3. Percentage of groups which identify different skills in the descriptions from the descriptive questions asked.

CONCLUSIONS

The trainee teachers give more importance to the description and definition than to the justification, especially in Primary education.

- A connection between the type of skill requested and the key idea considered can be seen, although this connection does not always coincide in the two groups.
- The teachers are not always conscious of the skill they request in the questions.

The conclusions show an area where more attention should be paid in teacher training, which should focus more on the importance of teaching how to give justifications, as they are essential for the understanding of the subject of human nutrition. This is relevant in Secondary teacher training, which should introduce justification, not only to aspects related to food and health, but also to the actual concept of nutrition and the functioning of the organs and systems involved. It is also relevant in Primary teacher training, as at an accessible level, children can understand what is happening in their bodies and/or justify why a good diet influences health.

This study is part of the Project INCITE08XIB106098PR, financed by the Autonomous Government of Galicia (Spain).

ASSESSING PROSPECTIVE TEACHERS' DIAGNOSTIC COMPETENCE

Abstract: Among the competences outlined to be relevant for pre- and in-service teachers, assessment and diagnosis are frequently mentioned. Teachers need to be able to identify pupils' conceptions as well as their learning outcomes and have to monitor pupils' learning processes in order to design instruction accordingly. Even though diagnosis plays an important role in teacher profession, it is rarely explicitly addressed in educational research. Here, we describe four different types of diagnosis: diagnosis of a status, of a solution process, of progression in status/solution process, and of learning processes. These different types can be assigned to the notion of summative and formative assessment, but at the same time help to describe more precisely the different diagnostic activities teachers should apply. In our project, they also serve as theoretical framework for the methods we use to investigate teachers' learning. Two cohorts of prospective teachers are monitored during their university education. Using questionnaires and video, we assess their prior knowledge and their progress for both content knowledge and those aspects of pedagogical content knowledge and pedagogical knowledge which are related to diagnosis. The main focus of this paper lies on our theoretical considerations and the methodological challenges we face. Some results will also be presented.

Keywords: Diagnosis, diagnostic competence, pre-service teacher education, assessment

During the last couple of years, an increasing number of research projects have addressed teacher profession and teacher knowledge (for an overview see e.g., Abell, 2007). Shulman's distinction between subject matter knowledge/content knowledge (CK), pedagogical content knowledge (PCK), and pedagogical knowledge (PK) (e.g., Shulman, 1987) is often used in these projects to describe teachers' professional knowledge. Within these competences, teachers' abilities to assess pupils' content specific knowledge and their learning processes are highly valued. Such a focus on pupils is a main prerequisite to design instruction with appropriate learning demand, for instance, by taking pupils' prior conceptions into account. Even though knowledge about pupils' learning and methods by which this knowledge can be achieved are considered to be important aspects of professional competences, they are typically not addressed in detail in recent research projects. In particular, diagnosis is not very well theoretically framed, neither is diagnostic competence. Therefore, the main aims of our project are to establish a distinction between different types of diagnosis in order to 1) describe corresponding teacher activities and their outcomes and 2) situate our own assessments of teacher learning. Furthermore, the distinctions are embedded into a model of (prospective) teachers' diagnostic competence which serves as a heuristic to analyze the expected progress prospective teachers make during their university education.

DIFFERENT TYPES OF DIAGNOSIS

Generally, when we refer to the notion of diagnosis we refer to all kinds of assessment which try to get an idea of a learner's current knowledge, her/his abilities, changes in knowledge and abilities, and the learning that takes place. Diagnosis is strongly related to the aim of improving education for the learner or a group of learners assessed. We stress the importance of diagnosis as a means to improve understanding of learning and effective instruction. With questionnaires such as the Force Concept Inventory (FCI, Halloun, Hake & Mosca, 1995, see item in Figure 1), researchers intend to assess conceptions pupils (and sometimes also teachers) possess at a specific point in time. For example, for the item presented in Figure 1 prospective teachers tend to choose solution D (incorrect) rather than solution C (correct). **Assessing the knowledge and abilities that learners have at a specific point in time is what we refer to as "diagnosis of a status."**

A woman exerts a constant horizontal force on a large box. As a result, the box moves across a horizontal floor at a constant speed "v_0".
The constant horizontal force applied by the woman:

(A) has the same magnitude as the weight of the box.
(B) is greater than the weight of the box.
(C) has the same magnitude as the total force which resists the motion of the box.
(D) is greater than the total force which resists the motion of the box.
(E) is greater than either the weight of the box or the total force which resists its motion.

Figure 1. Example of an item to assess student misconception in Mechanics (FCI, Halloun, Hake & Mosca, 1995)

T2: […] **Well, I would say greater**, isn't it?
T1: Greater? […]
T2: But, no, wait. Hold it. **Same magnitude, because the box is moving already. We don't have to accelerate it.** It says "the box moves at a constant speed", that is, it moves. (indicates movement on the table) **And we are right in the middle of the movement. Therefore, they have to have the same magnitude.**
T1: Well, you mean, it's the same as the example with the lorry, only different?
T2: I don't know, I don't think so. **But, if they had the same magnitude, then they would stand still, wouldn't they?** (indicates stopping with his hands)

Figure 2. Two prospective teachers (T1 and T2) discuss the task presented in Figure 1 (bold: indicates the solutions chosen by T2, switching from D to C and back to D).

In order to diagnose a status, researchers and teachers typically use a learner's assessment product such as a multiple choice answer, a short answer given to a question, a drawing, and so on. However, these products often do not give much information on how a learner has conceptualized the task. For example, they do not take into account the ideas that came into her/his mind and the operations s/he performed while solving the task, the cross-references the learner makes to examples s/he has worked on previously, and so on. Monitoring these processes in which a learner (or a group of learners) come(s) to a specific solution (the product) will give more insights into the opportunities and challenges a learner faces. In Figure 2, the dialogue of two prospective teachers who try to solve the task given in Figure 1 is presented. Even though these prospective teachers ticked "D" as an answer, prospective teacher 2 (T2) is able to develop a correct interpretation as well. Thus, instruction does not need to establish the idea on Newton's Third Law but has probably to use more examples in order to practice identifying how to apply this law. **Assessing a learner's performance (verbal and non-verbal, for instance tackling experimental equipment) while s/he tries to solve a specific task is what we call "diagnosis of a solution process."** Both, diagnosis of a status or diagnosis of a solution process, are directed towards assessing the knowledge and abilities a learner holds at a specific point in time. They play a dominant role in research and teaching.

In order to be able to say something about progress, assessment (either of the status or the solution process) has to be repeated after a specific span of time, using similar tasks than for the first assessment. It is typically assumed that learning has happened between these two different points of assessment, thus, a progress should have occurred. **The kind of assessment applied to diagnose changes in a status or a process is what we call "diagnosis of progression".** Diagnosis of progression is more common to research than to education in school, as teachers typically do not formally assess pupils' prior knowledge and its changes as a result of instruction.

Assessing the progression that has taken place does not offer insights into how this change has come about. Which intermediate steps were necessary? How was instruction utilized (which was helpful and in what way)? If a learner, for instance, is not able to pick the correct answer because s/he has not yet any idea of Newton's Third Law (see Fig. 1), how is an appropriate idea that leads to picking answer C developed? Assessing how learning occurs (not "just" changes or progression over a longer period of time) requires some sort of continuous measurement in order to trace how new or existing ideas are developed**. Assessing in which way new knowledge and abilities are established is what we call "diagnosis of learning processes"**. This assessment would monitor, for instance, *all* instances in which learners discuss Newton's Third Law during instruction (and, if possible, while doing homework on that issue). We know that this kind of diagnosis is rather complex, can be performed by teachers only informally and is rare in current research on pupil or teacher learning. However, even if it is rare, it is different from the other three types of diagnosis and the here presented distinction can also help to identify the projects which focus on this kind of assessment.

DIAGNOSTIC COMPETENCE

In our research project we assume that teachers are able to distinguish the four types of diagnosis described above and are able to apply them purposefully in order to evaluate and improve their instruction. Also, teachers should know about typical results, e.g., gained from research, and how these results are framed theoretically in order to develop appropriate instruction. Prospective teachers should, therefore, for instance, be able to…

…assess pupils' knowledge, abilities, interests, and self-concepts with appropriate tests or questionnaires. [diagnosis of a status]

…evaluate whether pupils work on tasks as expected/what kind of learning difficulties pupils encounter. [diagnosis of a process]

…explain levels which can be used to assess subject-matter and/or content-specific progression. [diagnosis of progression]

…monitor how a series of learning tasks help pupils to establish new competences. [diagnosis of learning processes]

…distinguish between different types of diagnosis and illustrate their distinctions with appropriate examples. [all types of diagnosis]

The standards are grouped together in a model of diagnostic competence (e.g. v. Aufschnaiter et al., 2009). All standards associated with diagnostic competence can be related to current ideas on PCK and PK. In addition, the model assumes that CK has an impact on the development of diagnostic competence, thus, it includes some standards on subject-matter competence which can be related to the idea of CK. Furthermore, the model includes some standards which refer to the outcomes of diagnostic competence in terms of using knowledge and abilities associated with diagnosis for the development of instruction. In addition to these three areas (diagnostic competence, subject-matter competence, and competence to develop instruction based on procedures and results of diagnosis) we assume that (prospective) teachers' attitudes/beliefs, motivation, self-regulation, and cognitive abilities have an influence on the development of diagnostic competence. It has to be noted that, so far, the model serves as a heuristic to explore teacher learning. We are not yet planning to evaluate the model, but are well aware that this needs to be the next step in our research plan.

SAMPLE

In our project two cohorts of prospective teachers (at the beginning typically about 20 years old) are monitored throughout their university education over a period of four years (10/2008-09/2012). Cohort 1 has started in 2008, cohort 2 in 2009. In Germany, all prospective teachers study two different subjects which they will then later teach at school. Here, in each cohort all participants study either two sciences as subjects or a science subject and mathematics. These prospective teachers are trained for middle and also partly for upper secondary level. Due to organizational aspects, we mainly gather data from prospective teachers who chose biology and physics as their future school subjects. Therefore, in this paper we concentrate on these two sciences and present how we explored different types of diagnosis, using both, instruments already established in other groups as well as instruments that have been developed by ourselves during the course of this study. "Diagnosis" occurs in two different ways in our project: (a) It is used to describe and promote teachers' diagnostic competence and (b) it is used as research method, in that we describe our own research in terms of diagnosis of a status or a process or progression or learning processes. In the following to sections we present how we use the different types of diagnosis in our research (b).

METHODS AND RESULTS 1: DIAGNOSIS OF STATUS AND CHANGES IN STATUS

Current research on teacher education typically uses paper-pencil-tests to assess teachers' current knowledge and (sometimes) its progress before and after specific instruction (more often differently experienced groups of teachers are compared). For instance, components of CK are assessed with TIMSS-items; in physics, instruments such as the FCI (Halloun, Hake & Mosca, 1995) or the test on electricity (Shipstone et al., 1988) are used to design specific instruments for teacher education (e.g., Olszewski, 2010; Riese, 2009). For PCK- and PK-components, there is an ongoing research aiming to establish reliable and valid items (e.g., Jüttner & Neuhaus, 2011, Olszewski, 2010; Riese, 2009).

In the past 3 years we have been using some of these instruments for our own diagnosis of prospective teachers' status with respect to their subject-matter competence and those components of PCK that are associated with diagnosis. These instruments are applied roughly once a year, starting with a large number of CK-related items and progressing slowly to PCK-items with increasing complexity. We use anchor items in all questionnaires in order to determine progress. For physics, the results (N=68) indicate, that at the beginning of their university education the prospective teachers hold similar misconceptions like pupils do. Our results also indicate that subject-matter knowledge in one area (here: mechanics) is not a good predictor for knowledge in another area (here: electricity), especially when scores in mechanics are low. We have a significant increase in the prospective teachers' knowledge after one year but cannot say what causes this increase as we were not able to diagnose the prospective teachers' learning processes throughout all related subject-matter courses. So far, our results on subject-matter knowledge explain (only) about 25% of variance in diagnostic competence. Interestingly, we were able to identify relatively high scores in subject-matter knowledge of individual prospective teachers while at the same time these participants score low in their diagnostic competence.

When searching for already established instruments for measuring diagnostic competence it turned out that most show at least two restrictions. First, almost all available instruments were designed for math or physics teachers. Instruments especially made for biology teachers seem to be rare (see Jüttner and Neuhaus (2011) for an example). Furthermore, all instruments mainly focus on knowledge *of* science (or PCK with reference to science content), but not to knowledge *about* science (and PCK including aspects of diagnosing, for instance, how well pupils perform an experiment or what their knowledge of scientific inquiry is) even though the latter has recently been stressed as an important goal of teacher education (e.g., AAAS, 2009; Millar & Osborne, 1998). Here, our aim was to establish a new instrument to diagnose the status of prospective teachers' abilities to assess pupils' scientific inquiry competence.

In our instrument we use the theoretically assumed and empirically proven four subskills of scientific inquiry, (see Möller & Mayer, 2009 for details; the rather practical skill "conducting an experiment" was not part of this study): (1) formulating scientific questions, (2) generating hypotheses, (3) planning an investigation, and (4) interpretation of obtained data. Pupils were given test items with a description of a specific biological setting (e.g., the number of wood beetles and woodpeckers in a forest) and were then asked either to formulate a question, to develop a hypothesis, to plan an investigation, or to interpret given data (see Möller & Mayer, 2009 for details). The pupils' answers were assigned to five *a priory* defined different performance levels in each subskill (questions, hypotheses, investigation, interpretation, see example in Table 1 for the subskill "generating hypotheses").

Table 1. *Description of competence levels for the subskill "generating hypotheses" (Mayer & Möller, 2009); level 5 is not used in our diagnostic instrument*

Competence Level	Description
1	Generate simple testable hypotheses without explanation
2	Generate hypotheses based on analogies from everyday life
3	Generate hypotheses based on biological concept knowledge
4	Generate hypotheses that are generalizable and/or quantifiable
5	Discuss alternative hypotheses

For our instrument in pre-service teacher education, the prospective teachers were given the test items that were handed out to the pupils, the pupils' original answers as well as the descriptions of the four levels (see Table 1). The prospective teachers were then asked to assign the pupils' answers to the appropriate performance levels. Thus, we used diagnosis of a status in order to diagnose the prospective teachers' ability to diagnose a status from learners' products (their answers). In total, 95 prospective teachers participated, each of them completing two different test-booklets. A test booklet focused on one subskill of scientific inquiry (for instance, on the formulation of an appropriate question) and contained in total 16 pupils' answers for different settings. Thus, each prospective teacher roughly assigned levels to 32 pupils' answers, of which 16 referred to one and 16 to another subskill of scientific inquiry.

Results demonstrate that prospective teachers were better in assigning pupils´ answers on lower levels than higher levels (compared to the assignments of a group of researchers). Furthermore, a more in depth analysis of the results shows that assigning levels to pupils' test answers in the subskill "interpretation of the obtained data" was significantly easier for the prospective teachers than in the subskill "planning an investigation". In order to get more information about the reasons for these results and to evaluate the validity of our diagnostic instrument we adjoined a diagnosis of the solution process in which the prospective teachers make their decisions on which performance level to choose. This was conducted by videoing them while working on the diagnostic test and talking about the correct assignment. First results regarding this indicate that the prospective teachers often have difficulties with the more complex and more detailed criteria of the high levels. Investigating the correlation between CK and the measured diagnostic competence of the prospective teachers, we found a significant but low correlation ($r=0,34$; $P=0,001$) between their knowledge of scientific inquiry (assessed with an instrument based on multiple choice tasks which are referred to the above mentioned four subskills of inquiry) and their ability to assign performance levels to the pupils´ answers correctly.

METHODS AND RESULTS 2: DIAGNOSIS OF SOLUTION PROCESSES AND CHANGES IN SOLUTION PROCESSES

In order to get a more detailed insight into how prospective teachers make use of their diagnostic competence they have developed so far and in order to check how their solution processes relate to their answers in the written test instrument, we videotaped groups of the participating prospective teachers while assigning the pupils' test answers to the appropriate competence levels. In physics, the videos are taken roughly two times a year, four settings in total, each centered around a task, and vary in length between 40-70 minutes. We assess the prospective teachers in groups of four, four groups per cohort. Task one and task three ask the prospective teachers to discuss pupils' answers on work sheets and to analyze a piece of video together with a transcript which documents pupils' group work. Thus, task one and task three focus on learning issues. In task two and task four the prospective teachers have to plan a lesson sequence and have to analyze a description of a lesson sequence. Thus, these two tasks focus on teaching issues. All prospective teachers who were documented with video have given their consent to be filmed. We asked those prospective teachers to be filmed who have participated in (almost) all written tests/questionnaires carried out so far. With the videos, we want to identify, for instance, whether the prospective teachers use empirical results or theoretical assumptions to justify their interpretations or decisions. We also aim to identify the amount of time our participants spend, for instance, on working on the tasks, clarifying subject-matter aspects, or talking about issues which are not related with the task ("off-task activities").

The main challenge we currently face with the videos is to set-up a coding scheme and manual that is in accordance with our model of diagnostic competence but is also able to describe the processes we observe – which does not always necessarily match the model's descriptions. All codes are applied on a 10-second-interval basis, each participant is coded individually. Coding always starts by identifying the focus of the activity. Here, we distinguish, for instance, between a focus on learning, a focus on teaching, or a focus on the clarification of the content of the task. The subsequent category "behavior" assesses whether a prospective teacher describes or plans pupil and/or teacher behavior. The category "teaching-learning-setting" is chosen whenever a prospective teacher elaborates on how the content of a lesson is ordered, what the characteristics of a learning task are, or which methods/media are chosen or have to be chosen, respectively. Finally, the system includes two categories which describe how the prospective teachers justify their interpretations or their decisions. These categories are important in our research as they offer, for instance, an insight into how often the prospective teachers base their interpretations on results and methods of diagnosis.

First and very preliminary results, so far only with a reduced data-set, indicate that the system can be applied successfully to the different groups and tasks we have. Roughly 45% of the time spent on the tasks is taken for reading and writing, about 35% of the time is used for discussing learning or teaching issues, and about 13% of the time is spent for clarification. To our own surprise, we can only identify about 1% of off-task activities (e.g., talking about their private plans for the weekend). Another surprising preliminary result is that our prospective teachers only spent about 3% of the total time justifying their interpretations or their decisions. Furthermore, the prospective teachers did only focus on pupils (in both their interpretations and their decisions) when the pupils were "present" in the tasks. That is, only if pupils' answers were to be discussed or an excerpt from a lesson includes descriptions of pupils' utterances and activities our prospective teachers included a pupil-oriented focus in their discussions. This is particularly interesting as a pupil focus was almost completely absent from the prospective teachers activities while planning a teaching sequence. We do not yet wish to give any possible interpretation for these results as we have not investigated all of our videos and have not yet related these results to outcomes of our diagnosis of status.

As the videos are taken throughout the whole university education we expect detailed information on how diagnostic competence progresses from comparing the processes of individual prospective teachers and their possible change and/or improvement between the different videos. However, we are not able to diagnose the prospective teachers' learning processes as we cannot monitor them continuously in those lectures which are related to the learning we want to assess.

CONCLUSIONS AND IMPLICATIONS

With its emphasis on diagnostic competence the project approaches important issues in teacher education with a novel focus. The distinctions made for diagnosis, the model for diagnostic competence and the instruments explored can help to broaden our idea of research on teacher education and may offer examples on how to assess teachers' learning in more depth.

TRAINING ELEMENTARY SCHOOL TEACHERS FOR THE USE OF SCIENCE MUSEUM FIELD TRIPS IN EARLY EDUCATION

Maite Morentin[1] *and Jenaro Guisasola*[1]

[1]University of the Basque Country (UPV/EHU)

Abstract: Science centers provide a good opportunity to work with science material out-of-school and should be included as a teaching-learning tool in science teacher education. This study analysizes the implementation of a teaching curriculum where elementary school teachers learn to integrate the teachings of scientific content using a field trip to a science museum. The results obtained show marked improvement in the experimental students' conceptions, so we think that the explicit integration of informal resources into the classroom curriculum offers significant improvements to the teaching-learning process that must be worked into the initial teacher training at all educational levels.

Keywords: initial teacher training, science museum, non formal education.

BACKGROUND AND PURPOSE

The education reforms put into place in the late 80s aimed to emphasize the way in which sciences were treated in order to improve the science teaching itself. The education standards of various countries stress the importance of introducing science as a creative process that develops theories and concepts to come up with tentative solutions to problems presented by both scientists and society. (National Science Education Standard, 1996; Spanish Science Standards, 2007).

Our interests center around the opportunity science museums provide for training elementary school teachers being locations with great potential for applying teaching materials to real world problems, both through experimental activities as well as expert reporting that delves deeper into scientific knowledge and its connection to society. This promotes a reflective practice in the field of science which the aim of complement formal education with informal contexts (Dierking et al., 2004).

Accordingly, studies conducted in the last few years on what is learned during field trips to science centers emphasize the importance of planning so that the perspective gained is effectual and lasting (Henriksen and Jorde, 2001). This planning should be explicitly emphasized within the school curriculum in such a way that activities are planned leading up to the field trip, during the visit itself, and then again upon return, to reinforce the experiences had while there (Anderson et al., 2003).

In prior studies, we have been able to substantiate that Elementary and Secondary School teachers in the Basque Country (Spain) does not adequately plan these visits and that their concept around the visit falls short of the research's recomendations. In other words, they view these field trips as a "free time activity", a type of extracurricular activity, that is, recreational and interesting in nature but not as a learning tool for their students (Guisasola and Morentin, 2010).

The science centers provide a good opportunity to work with science material out-of-school and should be included as a teaching-learning tool in science teacher education but teachers, in general, do not have the necessary strategies to prepare the visit properly, because at least in Spain, very few initial teacher training courses for primary and secondary implicate future teachers in learning experiences outside the classroom.

The study covered in this presentation analysizes the implementation of a teaching curriculum where elementary school teachers learn to integrate the teachings of scientific content using field trips to science museums. In particular, the study responds to the following questions of the investigation:

1) How do we design and implement a teaching curriculum for elementary school teachers which integrates science museum field trips with classroom education?
2) What do future teachers learn about organizing and developing science museum and center field trips?

RATIONALE

Scientific literacy has become one of the primary objectives for teaching science (Rocard et al., 2007), but different studies show that regardless of this new direction at different education levels in science literacy, both progressive and comprehensive implementation remains traditional and insignificant (Hofstein and Rosenfeld, 1996). In response primarily to the lack of adequate preparation for teaching science among Pre-service Elementary Teachers, Mellado (1998) points out the lack of understanding science as an activity immersed in a socio-cultural context, influenced by social and cultural values with its own process and characteristics.

These recommendations, together with other suggestions from the investigation on science museums (Falk and Dierking, 2000), make up the conceptual framework of this study and our own investigation centers on the need for the training of elementary school teachers to include knowing how to utilize the teaching and learning tools as offered by science museums and centers.

METHODS

In the University of the Basque Country Programme for Elementary School Teachers, a small curriculum of sciences is worked out for the second of the four years that make up the Degree. For this investigation, we have included within the training program a new teaching unit on the role that forces develop under daily situations but this educational unit involves also the preparation and visit to the *Eureka Science Museum* in relation to the topic of forces. We know that we cannot "teach" future teachers how to prepare a visit to the museum, in an abstract way, and so we decided to include that visit to the museum within the school curriculum as a part of scientific training for future teachers, so that in their future jobs they might have the necessary didactic strategies to design a visit to a museum helping students to really make the most of it.

The *Eureka SM of San Sebastian* is the unique science museum found in the Basque Country (see http://www.eurekamuseoa.es). It was inaugurated in 2001 as KutxaEspacio S.M. but it changed its name four months ago.

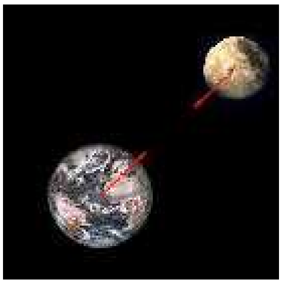
The teaching unit design covers the recommendations made by the investigation for science museum field trips, keeping in mind such aspects as integrating the visit to the science museum into the unit, performing activities prior to the visit, creating activities to perform during and after the visit, strategically working with subjects fitting the context of the museum and taking into account the ways of learning in out-of-school contexts.

So, the first result of this work is the actual educational unit or teaching material entitled "Forces in action", designed with the aim of working on the topic of forces and its didactics (topic included in the curriculum for our subject) whilst putting into practice some of the strategies required for preparing a visit to the science museum.

We chose the topic of "forces" due to the fact that *force* is one of the contents present in the Primary Education curriculum whose conception, whilst not simple, must be worked on from this stage. In addition, we know that one of the topics in the Primary curriculum that is most represented in science museums in general and in the Eureka museum in San Sebastian in particular is that of "forces and machines" with a large number of modules spread over several rooms. Finally, to finish justifying the choice of topic, we might say that "force" is one of the most researched concepts from the point of view of alternative ideas, and the bibliography tells us that poor results found in the students' conceptions could be improved by working on the force model from primary education.

Among the different activities making up the teaching sequence, some take place before the visit, others during the visit and others afterwards. We will give some examples of activities:

Example 1 (Activity 18.) In groups, answer these questions:



Is there a force of attraction between two apples?

What about between the Earth and the Moon?

Explain your answers.

This is an easy activity for before the visit, aiming to work on gravitational attraction. Students have to work in small groups, and after that there will be a brainstorming where they have to explain their answers.

Example 2 (Activity 26.) In groups,

Have you ever seen a bed of nails?

Imagine someone lying down on a bed of over 7000 nails. In the museum, anyone who wants to try can lie down and check the effect of the nails.

What are the existing forces?

Why do we feel no pain?

Will it depend on our weight?

This activity refers to the 'bed of nails', it is also an activity to be done beforehand and it can be used to relate the concepts of force and weight with pressure. The photo shows the exhibition that students will see in the SC, and they have to answer those questions previous to the visit and after it; then they will compare their own answers and they will understand the concept they had learned in the museum.

The last example is an activity for after the visit where students have to reproduce an experiment seen in the museum.

Example 3 (Activity 29.) **Eureka!**

You have to carry out a similar experiment to what we saw in the SC (Archimedes Principle). This involves calculating the masses and the weights of the different objects in both the air and the water but you have to design the experiment yourself (in groups).

1. **Design and write down the experiment (steps and materials)**
2. **Carry out the experiment, noting down the data obtained**
3. **Explain what happened, draw conclusions and relate it to what was done in the SC**

In this activity students have to design the experiment, they don't have the "recipe", and they have to remember what they made in the museum and make their own practice; then they have to explain their own conclusion to their mates.

The all teaching unit was worked with a group of second year teaching students during the regular teaching year, 6 sessions of 2 hours (field trip included). After that and to evaluate the possible changes in the students' conception of science museum field trips used as a learning tool, a survey of 5 open-ended questions pre-test and post-test was designed for this group; once all questions were collected, the answers were analyzed and categorized after encoding the ideas, noting common patterns and grouping principle tendencies (Cohen et al., 2007). Along these lines, the frequencies of each category were calculated to check the differences between pre- and post-test, using the Hake index (1998) to calculate gains.

RESULTS

The results obtained show marked improvement as significant changes were reached in the experimental students' conceptions. Some results tables are shown.

What features should a SC visit have to be effective?	PRETEST N= 38	POSTEST N= 36
Correct answers: Visit with activities before and after/ related to classroom topics	**4 (10.5%)**	**13 (36%)**
Incomplete answers: It should be useful for learning, with complementary activities (workshops, demonstrations…)	**8 (21%)**	**3 (8.3%)**
Alternative answers: Possibility of experimenting, practice, guided…	**26 (68%)**	**18 (50%)**
Unclassified answers or Don't know/No answer	**--**	**2 (5.5%)**

We asked our students about the characteristics that a visit should have to be effective and the correct answers increased from 10% to 36% after working on the DU; this positive result is ratified by the drop in the percentage of alternative answers (from 68% to 50%) referring uniquely to the practical and experimental aspects of the visit, as well as the drop in the percentage of incomplete answers.

Visits to SC are useful when…	PRETEST N=38	POSTEST N=36
Correct answers: They are used for learning related to the curriculum/ Teachers prepare them previously in the classroom	**3 (7.9%)**	**11 (30.5%)**
Incomplete answers: They are used to check what was studied in class / To learn more (without specifying)	**20 (52.6%)**	**13 (36.1%)**
Alternative answers: They are used to arouse interest in science/ They are fun, entertaining, recreational	**12 (31.6%)**	**11 (30.5%)**
Unclassified answers or Don't know/No answer	**3 (7.9%)**	**1 (2.9%)**

In this second table, results are about the usefulness of these visits. As in the pre-test, this last percentage is so small (7.9%), we might conclude that the students' initial conception has evolved in a greater proportion towards a more complete conception of the visit; the percentage of correct answers is about 30% after classes. The drop in the percentage of incomplete answers also ratifies this improvement, but it can be seen that is difficult to modify "common sense" conceptions (alternative) that only include some recreational aspects of these visits (from 31.6% in the pre-test to 30.5% in the post-test); this result fits whit others shown in previous researches (DeWitt & Osborne, 2007; Olson et al., 2001).

After the implementation of the teaching unit, these students rated the science museum field trips as very useful not only for their value as an experimental work experience, but for their contribution to the contextualization of science in the school's curriculum. Their initial conception has been changed and they have reflected about the work of the teacher that has to prepare the visit properly for their students to be effective.

CONCLUSIONS AND IMPLICATIONS

Applying the teaching unit to second year Elementary Teachers students has incited an evolution in the students' conception from a common sense idea in which "the field trip serves as a way to have a good time and motivate the students" to one we had aimed for, "a field trip is fun, but you can learn adequate and accurate information if you prepare for it". In their responses students demonstrate that they learned to use certain tools recommended by the research to prepare school science center field trips, although it is difficult to change some common sense conceptions, as we have said.

We are aware that this experiment has been carried out within a very specific context and conditions, but we think that it ratifies our proposal significantly. So we can conclude that:

- The visit to the science centre has to be included within the school curriculum to be effective.

- If future teachers have experienced how to prepare visits to the museum in their initial training, we think that it will be easier for them to put this into practice in their professional future.

Although we know that other variables exist, we think that the explicit integration of informal resources into the classroom curriculum offers significant improvements to the teaching-learning process that must be worked into the initial teacher training at all educational levels.

FUTURE TEACHERS' VIEWS ON COMMUNITY PROJECTS AS LEARNING ENVIRONMENTS FOR SCIENCE EDUCATION

Lidia Ochoa Cañigueral and Anna M. Geli de Ciurana
Institute of Educational Research - University of Girona (Catalonia/Spain)

Abstract: This paper presents some findings of the action-research process that accompany the project *Girona, seed city for Science.* It focuses on future teachers' views on community projects as learning environments for science education and sustainability. It also identifies implications for pre-service teacher education reform. The research seeks to explore the opinion and perceptions of the future teachers as participants in the community project for science education. The science education community project *Girona, seed city for science* began as part of the European Project *Pollen, Seed cities for science: a community approach for a Sustainable Growth of science education in Europe.*

Keywords: Pre-service teacher education, community project, science education, learning environments, student involvement.

BACKGROUND, FRAMEWORK, AND PURPOSE

This text focuses on future teachers' views on community projects as learning environments for science education and sustainability and it identifies implications for pre-service teacher education reform.

The purpose of this paper is to present some findings of the action-research process that accompany the development of the project *Girona, seed city for Science*. The research seeks to explore the opinion and perceptions of the future teachers as participants in the community project for science education. The science education community project *Girona, seed city for science* began as part of the European Project *Pollen, Seed cities for science: a community approach for a Sustainable Growth of science education in Europe.* The Rocard Report (2007) featured it as one of best experiences in science education in Europe.

Pollen is a European project for research and development funded by the Sixth Framework Programme of the European Commission which took place between 2006 and 2009. Twelve countries participated as partners and during the three year duration of the financed project twelve initiatives were developed simultaneously: a seed city for science in each country (the Spanish seed city was Girona). Once the European funding ended, the local partners in Girona decided to continue it with local resources. The community project aims to stimulate and support science teaching and learning in primary schools (children aged 3 to 12 years) by promoting hands-on and inquiry-based science education for sustainability. The project involves local authorities, the faculties of education and sciences and also present and future teachers in a sustainable framework for science education through a child-centred approach starting in school and extending to the whole city.

The main activities of the community project are initial and in-service teacher education seminars and community events such as *the Science Fair for Little Big Scientists*, the *Researchers' Night* or the *Bio-Market day*. In addition, the project offers advice and guidance to the participant schools and teachers on a request basis.

The future teachers are university students enrolled in teaching degrees (early childhood teacher studies and primary education teacher studies), and they can participate in the project basically in two different and complementary ways. On one hand, from 2008 until nowadays the first year's students design, implement and evaluate a science workshop at the Science Fair. This is part of their compulsory practical work of a science teaching course. On the other hand, they can be involved in the project as volunteers when they are in the last years of their degree and become part of the organizing committee of community events and support other activities such as training sessions or schools visits.

RATIONALE

An important part of the research being conducted is aimed at developing a proposal to improve the initial teachers' education, above all related to the pre-service teacher education reform. Higher Education Curriculums have recently changed in Europe as a response to the new European Higher Education Area. Besides, new educational and political trends are forcing curriculum changes all over Europe and other parts of the world (Jenkins 2009). The Spanish and Catalan curriculums – for all levels and stages of education, from kindergarten to University- have shift from a conceptual-content centred point of view to a competency-based approach. A competency is determined by the mobilisation of a combination of cognitive abilities and practical skills which are interrelated: knowledge (including tacit knowledge), motivation, values, emotions and other social, behavioural components which may be mobilised for effective action (OECD, 2002).

Teacher competences are then, by definition, developed, shown and demonstrated in action. Our hypothesis is that community projects can be used as real context learning environments for pre-service teachers while the project itself benefits from the participation of university students. There are some projects and researches that have tackled this new curriculum orientation in the field of teacher education and sustainability such as CSCT (Sleurs 2008) but more research is needed in order to better understand the processes involved and their implications in the organization and implementation of the teaching and learning environments and activities.

The purpose of this research is to gain knowledge concerning the process of student involvement, specially their own perceptions and vision of their participation in order to improve the project itself and take advantage of it as a powerful learning environment for initial teachers' education.

The research seeks to explore the opinion and perceptions of the future teachers **as participants** in the community project for science education, in order to answer the following research questions:

- What learning opportunities are created through the community project?
- What can the University do to support IBSE –ES oriented- in schools while taking advantage of the process as a powerful learning environment?
- What changes should we introduce in pre-service teachers education to improve the situation?

METHODS

The research aims to track systematic formative evaluation of the implementation process and project development Girona, seed city for science. We share the vision of Vidal and Mateu (1997) according to which "evaluative research is a set of processes for obtaining and analyzing information to make judgments about the object, phenomenon or process under investigation as part of decision-making process itself".

This is an evaluative research with a clear focus on action research approach. As Noffke (1997) stated it may help us -researchers and practitioners- learn to participate and change our practices so as to fit our personal settings by creating conditions for change at three levels - personal, professional and political. We share the idea that an appropriate form of professional development, such as Education for Sustainability in itself, must be contextualized, and respectful towards the creation of knowledge of those involved in the process.

During the process, three action-research cycles (Elliott, 2001 and Martí, 2002) have been completed, each one matching the academic courses 2008-09, 2009-10 and 2010-11. The analysed data used in this paper is from the two firsts cycles (from 2008 to 2010).

The methods used to obtain data are mainly qualitative. We used individual questionnaires (with open ended questions) and conducted few semi-structured interviews – 6 individually and 3 collectively- to pre-service teachers who were volunteers in 2008-2009 and 2009-2010 (32 students in total). Both the questionnaires and interviews had a double objective: on the first hand to identify opinions and perceptions about the tasks developed within the project; and on the second hand and also very important, to foster self-reflection and awareness about the learning process involved. There was also a documental review and participant and non participant observation to complement and contrast data.

The data has been analysed inductively, following Grounded theory, from a constructivist perspective (Charmaz, 2006). Initial findings were shown and discussed with the group of volunteers to add validity and to share the process and results with the participants.

RESULTS

According to students' own reflections, the volunteers raised three basic issues when deciding to participate. They all first highlighted their will to get involved in light of last year positive experience (compulsory participation). Secondly, they consider that the Science Fair event in particular and the community project in general offered a very good framework for introducing the participation of different groups and individuals in a local project related to their future profession and they wanted to be part of it. And finally, they pointed out their motivation to acquire more practical experience in contact with children. Only few students mentioned they volunteered because they liked science and/or science education.

The main reasons obtained to the question why did they decide to participate, were the following:

- A very positive experience in their first year (compulsory participation).
- To acquire more practical experience in contact with children.
- The project is interesting/useful and directly related to their future profession & the methodology engaging.
- They liked the people involved and the mood/atmosphere.

Only four students mentioned:

- Curiosity/interest in science.
- Lacking knowledge in science & science education.

<u>Students' quotes:</u>

- *"I believed that [the project] is really useful and it accomplish the goals that where set at the beginning. Besides, I agree with the methodology used and that's one of the most important things."*
- *"I decided to participate because it has been the first and only time that someone offers me a real opportunity to learn participating actively in such a project".*
- *"I decided to join because this opportunity was offered and it was a good way of being with children and that's something we rarely do here at the Faculty... And to learn having fun"*
- *"We have engaged each other talking about it, I think that as future teachers it's crucial we get interested in this kind of projects and get used to kids"*

<u>Professional, formative and personal gains</u>

When talking about what had they learnt in terms of "professional and formative gains", our participants mentioned the following ideas:

- Practical knowledge and skills development with children (design, prepare, test and assess activities)
- Learn to be a reflective practitioner

- Importance and usefulness of experimentation & inquiry (as something new/different/stimulating)
- Knowing how a community project works and its importance.
- New ideas, experiences and resources/materials
- Compare and contrast different ideas about science & education
- Meeting new people and getting to know others better.
- Scientific knowledge

And they were also asked to give their opinion about the possible “personal gains” obtained through this experience. They mentioned and talk about:

- Personal satisfaction: to be part of something big, important, useful and successful.
- Self-confidence.
- Personal contacts, bonding, high value of companionship and collective work.
- Lots of fun and good memories.
- New perspective about science (more open and positive).
- Realization & discovery of the power of engagement & motivation.

The team of volunteers gained autonomy and initiative as the academic year advanced and that generated a powerful sense of belonging to a learning community outside mainstream classes. That was identified as a new and highly positive experience for all the volunteers. The majority pointed out the value of dealing with their own interests and ideas while trying to fulfil the project goals. Some of them were puzzled by the fact of finding themselves asking for more “theory” as they found they were lacking of it when designing and implementing activities. They said they learnt a lot more when participating as volunteers rather than in ordinary courses. When asked about the reason why that might be, they answers were related to motivation, the sense of reality and meaningful learning. They recommend this experience to other students above all because it is one of the very few opportunities to practice their skills with real children and because they felt they were valued and trusted.

CONCLUSIONS AND IMPLICATIONS

From the results obtained during the action research process, we can say that the community project under study has great potential as a learning environment that complements the pre-service teacher education. This potential is based on one of their essential characteristics: it is a real project, adapted and developed based on the needs of the community participating. Each person or group involved contributes to the development process of the project and collective learning is being created together. Student teachers bring a huge dose of energy and enthusiasm and receive practical experience in a professional environment and very intense personal experiences.

During the 2008-2009 academic year ten volunteers participated and the following year were over thirty and they continue to increase. This trend is a clear indicator of the success of the initiative, and it is even more because students do not receive anything –

material or academically- in exchange for their participation, apart from the experience itself. Only a little tiny minority joined the project because they liked science, so that means we can take advantage of community projects to make science education more motivating to future teachers. This is a collective learning process and the only way to meet the challenges and opportunities is to keep learning together.

A SURVEY OF PRESERVICE SCIENCE TEACHERS' CONCEPTIONS OF RESEARCH METHODS COURSE

İsmail ÖNDER[1] and Şenol BEŞOLUK[2]
[1]Sakarya University, Faculty of Education, Secondary Science and Mathematics Education, Turkey.
[2]Sakarya University, Faculty of Education, Elementary Science Education, Turkey.

Abstract: Research skills are important in teaching profession as in any other professional field. Therefore, preservice science teachers should know what research methods are and how the knowledge related to research methods can be used in teaching profession. For that purpose a research methods course was included to preservice science teacher education curriculum in Turkey. The aim of the present study is to investigate preservice science teachers' conceptions of research methods course. A questionnaire composed of five open ended items was administered to purposively selected 31 preservice science teachers. Preservice science teachers indicated that the course can be useful mainly for academicians and researchers. Furthermore, only minority of the participants indicated the importance and usefulness of the course content for teaching profession.

Keywords: Research methods course, preservice science teachers, undergraduate course, science teacher education, research skills

INTRODUCTION

The field of education continuous to grow so rapidly with regard to both the knowledge it contains and the methodologies it employs (Fraenkel & Wallen, 2006). Therefore the ability to do research becomes extremely important for science teachers. In fact, research skills can be of great benefit to any professional person (Galpin, Hazelhurst, Mueller & Sanders, 2004). Since 2006 there is a scientific research methods course in preservice science teacher education curriculum in Turkey. Scientific research methods course is a course for 3rd year (5th semester) undergraduate students majoring in science education (YÖK, 2007). Therefore, preservice science teachers started to take this course since 2008. It involves 28 hours of lectures. The aims of the course are to provide students with the basic information needed to understand research process, to use the knowledge to design their own research investigation and permit students to read and understand the literature of educational research. Furthermore, this course aimed to give students opportunities to develop and practice a range of research related skills such as: critical thinking, critical reading, the ability to present a logical and coherent argument, presentation skills, looking events from a broader perspective etc. It is therefore important to present whether the course achieved its aims and whether students attach enough importance to the course and whether they are aware of its benefits while they are performing teaching profession. Therefore, the objective of this paper is to stimulate discussion on research methods education in preservice science teacher education program by obtaining students opinions about the course.

METHOD

A qualitative research method was chosen to enable the participants to express their own views and to use actual participant statements as data. Therefore, a questionnaire was constructed to determine pre service science teachers' views regarding Scientific Research Methods course by the researchers.

Sample

Purposive sampling methodology was followed. Students who have enrolled to Scientific Research Methods course were the participants of the study (N=31). The age of the students ranged from 20 to 22 yrs. Of the 31 students, 25 were female and 5 were male.

Data collection instrument

A questionnaire consisting of 5 open-ended questions was administered to each participant at the end of the course. The questions of the questionnaire are provided below.

- What is your opinion about having a research methods course in preservice science teacher education curriculum?
- Do you think that the information provided in the course will help you in daily life? Please explain.
- Considering the knowledge you have acquired in the course, will it be beneficial while performing the teaching profession?
- At most who do you think can benefit from information provided in the course?
- Where and for what purpose do you think the information provided in this course can be used at most?

Data analysis

The participants written responses were analyzed using content analysis. Through multiple passes over written responses a set of tentative categories were developed. Once these tentative categories were developed, researchers reread the participants written responses individually in order to code for specific instances of the categories. A joint reading followed to validate the categories gleaned from the first readings and to settle any disputes regarding coding. The inter ratter reliability for coding the participants' written responses to the open ended questions was 90.0%. Next, participants' representative responses that identify the categories and some outlying responses that carries significant and powerful message were selected.

RESULTS

The findings of the study are presented according to the themes revealed in participants' written responses to the open ended questions. Excerpts from their responses are included to clarify the thematic findings.

Question #1: What is your opinion about having a research methods course in preservice science teacher education curriculum? 74% of the participants indicated that there should be a course like that in the curriculum. However, the remaining participant considered the course as unnecessary. The views of the participants who considered the course as necessary mainly focused on enhancement of professional competence (f=6), necessity for academicians (f=6), planning and conducting a scientific research (f=6), and scientific thinking in solving a problem (f=3). The views of those who considered the course as unnecessary were luck of necessity of the course content for teaching profession (f=4) and complexity and detailedness of the course content (f=3).

Question #2: Do you think that the information provided in the course will help you in daily life? Please explain. 42% of the participants indicated that the information provided in the course will help them in daily life and remaining 58% indicated an opposite view. The view of those who thought the course as helpful for daily life generally focused on improvement of the skill of looking events from a broader perspective (f=5), development of analytical thinking (f=3) and preparation of the homework's (f=3). The views of those with negative opinion mainly cluster in fallowing categories: unrelatedness of course content with daily life (f=6) and lack of scientific research in daily life (f=7).

Question #3: Considering the knowledge you have acquired in the course, will it be beneficial while performing the teaching profession? 20 participants indicated that it will be beneficial, but the remaining participants indicated that it will not. The views of participants who said it will be beneficial mainly clustered on fallowing categories: conducting a research (f=8), assessment and evaluation (f=9), determining and finding solutions to educational problems (f=3) and ways to access information (f=4). The view of participants who said it will not be beneficial mainly categorized as follows: needlessness for teaching profession (f=4) and lack of application of knowledge (f=2).

Question #4: At most who do you think can benefit from information provided in the course? Participants indicated that academicians (f=15), graduate students (f=11), researchers (f=8), teachers (f=6) and preservice teachers (f=1) can benefit from information provided in the course at most.

Question #5: Where and for what purpose do you think the information provided in this course can be used at most? Participants' indicated that information provided in the course can be used in planning and conducting research (f=30), analysis of scientific data (f=7), writing a thesis/book/article (f=8), graduate courses (f=2), universities and research centres (f=10), and performing teaching profession (f=4).

DISCUSSION

Several researches indicated that students who attended research course had more positive attitudes towards research (Pearcey, 1995) and felt that they were better able to use research to improve their skill for their profession (Adamsen, Larsen, Bjerregaard & Madsen, 2003; Lacey, 1996). It is clear from the results, that overall, the students felt that the course can be useful mainly for academicians and researchers. Only minority of the participants indicated the importance and usefulness of the course content for teaching profession. However, most of them were unaware of the importance of research methods for teaching profession. This result could be attributed to the instruction, delivery of the content and inadequate course hours. The instructions are generally carried out by lecturing in two hours/week. Therefore, there was not enough time that can be spent for applications in which preservice science teachers can apply theory into practice, particularly related to field of education. Although some participants indicated that the course enhanced their skills such as looking events from a broader perspective, majority of them indicated that the course content is not related or beneficial for daily life and they also indicated that the information provided will be manly beneficial for academicians and researchers. Therefore, preservice science teachers were not aware of the usefulness of the course content for both daily life and teaching profession. These results present the necessity of further research about the effects of the course and how this course should be taught and what should be the course content and course hours. Adding application hours in addition to theoretical hours to the course should be discussed.

PRESERVICE SCIENCE TEACHERS' CONCEPTIONS OF ANALYTICAL CHEMISTRY

İsmail ÖNDER[1] *and Şenol BEŞOLUK*[2]
[1]Sakarya University, Faculty of Education, Secondary Science and Mathematics Education, Turkey.
[2]Sakarya University, Faculty of Education, Elementary Science Education, Turkey.

Abstract: Subject matter knowledge is important for teachers while they are performing their profession. In elementary level, teachers also should be able to provide answers for some daily life events and should be able to use daily life samples while they are teaching. This study aimed to investigate preservice science teachers' conceptions of analytical chemistry. A questionnaire composed of open ended items was administered to purposively selected 40 preservice science teachers. Results indicated that preservice science teachers think that the course is difficult and the content is detailed. Although some of them indicated that analytical chemistry knowledge is not required while they are teaching in elementary level, many others indicated that the course enhances their subject matter knowledge, problem solving skills and laboratory skills. Furthermore, majority of participants were not able to present enough number of appropriate examples for how analytical chemistry knowledge can be used in daily life.
Keywords: Analytical chemistry, pre-service science teachers, undergraduate course, daily life examples, pre-service science teachers' conceptions

INTRODUCTION

In recent years, researchers have shown a growing interest in the knowledge base of preservice science teachers. Preservice science teachers' conception of teaching and learning science or their views on teaching science or the ways they construct knowledge about teaching were analyzed by researchers (Van Driel, De Jong & Verloop, 2002). Many researchers also investigated the subject matter knowledge of preservice science teachers (Haidar, 1997). Subject matter knowledge is a key concept for science teachers while they are performing their profession. Therefore, science education programs include various chemistry, biology, physics and mathematics courses. The content of these courses is one of the major factors that empower students' subject matter knowledge that is important for teaching profession. Therefore, preservice science teachers receive several chemistry courses and analytical chemistry is one of those courses provided in the Turkish science teacher education program.

Analytical chemistry is concerned with the chemical characterization of matter and qualitative/quantitative analysis of it (Yuzhi, 2003; Skoog, West, Holler & Crouch, 2004). Analytical chemistry is a course for 2nd year (3th semester) undergraduate students majoring in science education (YÖK, 2007). It usually involves 22 hours of lectures and 22 hours of laboratory work. Most existing textbooks on analytical chemistry divide analytical science into fundamental and instrumental aspects (Otto, 2001). The content of the course in science education is mainly concerned on fundamental aspects such as gravimetric and volumetric analysis. Furthermore, teaching and learning of analytical chemistry is carried out using a didactic approach. Instructors deliver formal lectures to transmit knowledge; students receive it passively and are then expected to produce it accurately in the examinations. In the laboratories preservice science teachers perform experiments related to fundamental analysis and while performing these experiments they use commercial chemicals and daily life samples are generally not used in the analysis.

Analytical chemistry has a broad and detailed content and can be used in many fields (Valcarcel, 1992). Since science teachers will not serve as a chemist they do not have to know all the content in detail. However, the course provided in preservice science teaching program is similar to that provided in other departments. This detailed content needs to be criticized and some applications that require them to use daily life samples should be included. Therefore, in this study it was aimed to investigate preservice science teachers' conceptions of analytical chemistry and benefits of analytical chemistry knowledge to science teachers while teaching. Moreover, it was investigated whether they can provide examples of analytical chemistry applications in daily life.

METHOD

A qualitative research method was chosen to enable the participants to express their own views and to use actual participant statements as data. Therefore, a questionnaire was constructed to determine pre service science teachers' views regarding analytical chemistry course by the researchers.

Sample

Purposive sampling methodology was followed. Students who have enrolled to analytical chemistry course were selected as a sample of the study. Therefore, participants in this study were 40 pre-service science teachers enrolled in a one semester analytical chemistry course. The age of the students ranged from 19-21 years. Of the 40 students 29 were female and 11 were male.

Data collection instrument

A questionnaire consisting of open-ended questions was administered to each participant at the end of the course. The questions of the questionnaire are provided below.

- What are your positive views on analytical chemistry course?
- What are your negative views on analytical chemistry course?
- Is it necessary to include analytical chemistry course to science teacher education curriculum?
- Where do you think you can benefit from what you have learned in the analytical chemistry course while you are performing teaching profession?
- Please provide 10 examples on how analytical chemistry can be used in daily life.

Data analysis

The data collected from the open ended questions were analyzed by first conducting multiple passes through all written responses to each of the five questions. Each written response had been transcribed and categorized by question. Using interpretive content analysis participants' responses for common themes were analyzed by counting the appearance or frequency of specific units. Both researchers compared the themes identified and negotiated on these themes until they achieve consensus. The central themes were used as categories in further investigations. Then, a coding schema to track the thematic categories that emerged from participants' written responses was established. The written responses were reread and thematic indicators were count independently by each researcher. The inter rater reliability for coding the participants' written responses to the open ended questions was 90.0%. Next, participants' representative responses that identify the themes and some outlying responses that carries significant and powerful message were selected.

RESULTS

The findings of the study are presented according to the themes revealed in participants' written responses to the open ended questions. Excerpts from their responses are included to clarify the thematic findings.

Question #1: What are your positive views on analytical chemistry course? Participants' positive views mainly focused on usefulness of laboratory experiments (f=17), development of problem solving skills (f=14), enhancement of subject matter knowledge (f=10), helpfulness in daily life (F=10) and contribution to professional competence (f=5).

Question #2: What are your negative views on analytical chemistry course? Participants' comments generally focused on the detailed content (f=18) and difficulty of the course (f=13). Specific comments included: "Analytical chemistry course is to detailed for us", "I have difficulty in understanding what is taught". Few comments focused on the length of numerical procedures, work load, boringness of the course and similarity of the content with general chemistry course.

Question #3: Is it necessary to include analytical chemistry course to science education curriculum? Why? Most of the participants' (N=31) comments focused on the essentialness of the course. The main reason provided was that the course develops and increases the level of professional competence and their laboratory skills. Participants who said it is not essential mainly indicated that the content of the course do not match up with the content they will teach in elementary classes. A specific comment included: "elementary education program do not includes subject that require application of acquired knowledge in this course".

Question #4: Where do you think you can benefit from what you have learned in the analytical chemistry course while you are performing teaching profession? Participants' positive opinions clustered manly in three themes which are master the content (f=12), laboratory applications (f=21) and professional competence (f=22). Some students indicated that they will not benefit from analytical chemistry content while they are performing their profession. The main reason they provide was "we will not teach in elementary level in that detailed way".

Question #5: Please provide 10 examples on how analytical chemistry can be used in daily life. Participants' responses were grouped according to the number of appropriate examples. None of them were able to present appropriate 10, 9 and 8 examples. The frequency of appropriate examples is as follows: seven examples (3), six examples (4), five examples (3), four examples (9), three examples (9), two examples (7) and one example (4). Interestingly one participant indicated that "there is no example in daily life in which analytical chemistry knowledge can be used".

DISCUSSION

Preservice science teachers indicated that analytical chemistry course is helpful for the development of laboratory skills and subject matter knowledge. Therefore, they acquire necessary skills for teaching profession and increase their professional competences. However, they also indicated that analytical chemistry course is difficult and the content is too detailed. Furthermore, some of them said that they will not teach science in elementary level in that detailed way so detailed analytical chemistry knowledge is useless. The results also presented that preservice science teachers were not able to present appropriate examples for the usage of analytical chemistry knowledge in daily life. The content of the analytical chemistry provided in preservice science teacher education program as the preservice science teachers indicated is to detailed, heavy and the content is not so related with daily life. Therefore, the content of the analytical chemistry should be reevaluated and it should be arranged so that to include more daily life examples and applications. These will probably help preservice science teachers in both better understanding of the content and increasing their professional competence. Therefore, theoretical courses provided should comply better with actual professional needs.

POTENTIALS OF LERNWERKSTATT (OPEN INQUIRY) FOR PRE-SERVICE TEACHERS' PROFESSIONAL DEVELOPMENT

Sandra Puddu[1], Erika Keller[2] and Anja Lembens[1]
[1]Austrian Educational Competence Centre Chemistry (AECC-Ch), University of Vienna
[2]Austrian Educational Competence Centre Biology (AECC-Bio), University of Vienna

Abstract: In the debate about scientific literacy, the OECD considers an adequate understanding of science to be essential for becoming a reflective citizen, as it is an important basis for decision-making. Learning science through open inquiry is one contribution to reach this goal. Conducting open inquiry at school is a challenging task for teachers. To support them an appropriate learning environment for pre- and in-service teacher education needs to be provided. One learning environment to experience open inquiry and to prepare teachers for scaffolding their students which is offered by some universities in Germany, Austria and Switzerland is called Lernwerkstatt. The German term Lernwerkstatt seems to be the most appropriate one as there is no adequate translation.

To fathom the potentials of a Lernwerkstatt interviews with ten heads of Lernwerkstatt at universities were conducted and analyzed. In this paper the personal theories found in the interviews concerning the professional development through Lernwerkstatt in pre-service teacher education are presented. The personal theories found in the interviews could be related to theoretical backgrounds. Those are phenomenology, situated learning, learning environment, scaffolding and inquiry learning. Standards for pre-service teacher education were added to the analysis as a normative frame.

The results suggest that Lernwerkstatt is a learning environment where open inquiry can be experienced and one's own learning can be reflected. The interviewees stated that the experience of open inquiry makes pre-service teachers more aware of potential difficulties in learning processes and heightens the appreciation for these processes. The interviewees assume that pre-service teachers who have experienced learning in a Lernwerkstatt would use open inquiry in schools more frequently than pre-service teachers who did not have the opportunity to attend Lernwerkstatt courses.

Keywords: Open inquiry, pre-service teachers, teacher education, Lernwerkstatt

BACKGROUND, FRAMEWORK AND PURPOSE

In a modern society, life requires an adequate understanding of science and technology (NRC, 1996). It is important to be able to think creatively, solve problems and make decisions. In this context, scientific literacy is necessary to empower people to become responsible citizens (NRC, 1996; OECD, 2006). One way of becoming scientifically literate is to learn science through inquiry (NRC, 2000). For the implementation of inquiry learning into the classroom the education of (prospective) teachers should put greater emphasis on this aspect. In the National Science Education Standards the National Research Council (NRC) points out: *"[...] professional development must include experiences that engage prospective and practicing teachers in active learning that builds their knowledge, understanding, and ability"* (NRC, 1996, p. 56). Accordingly, Lernwerkstatt could be an adequate learning environment where pre- and in-service teachers can experience open inquiry. The term Lernwerkstatt could be translated as learning workshop but that is a very general term and is not considered as synonymic. Therefore, the German term is used. In this paper, the focus lies on pre-service teacher education.

There is not much literature about the theories behind Lernwerkstatt. Therefore, the main purpose of this study is to figure out which personal theories the heads of Lernwerkstatt have and to correlate them to established theoretical backgrounds to evaluate if Lernwerkstatt is qualified as a learning environment for professional development.

RATIONALE

The Lernwerkstatt concept was developed by Karin Ernst in Berlin, Germany, in 1980, mainly based on the New York workshop centre concept of Lillian Weber (Ernst, 1996; Weber, 1977). A Lernwerkstatt is described as a room where learners encounter stimulating phenomena, objects and materials which are supposed to trigger questions in their own field of interest for them to work on. In that room there are consumables like paper, cardboard, glasses, rubber bands, corks and so on, tools like hammer or cutting blades to start immediately with an inquiry.

Two key elements of Lernwerkstatt can be extracted from the literature:

- individual open inquiry learning opportunities are provided (Hagstedt, 2004)
- facilitators or coaches are needed who scaffold the learners' inquiry process (Zocher, 2000)

Inquiry in the classroom can be described by four levels (Blanchard et al., 2010) shown in Table 1.

	Source of the Question	Data Collection Methods	Interpretation of Results
Level 0: Verification	Given by teacher	Given by teacher	Given by teacher
Level 1: Structured	Given by teacher	Given by teacher	**Open to student**
Level 2: Guided	Given by teacher	**Open to student**	**Open to student**
Level 3: Open	**Open to student**	**Open to student**	**Open to student**

Table 1: The levels of inquiry (Blanchard et al., 2010, p. 581)

At level zero, the three key elements "source of the question", "data collection methods" and "interpretation of results" are given by the teacher whereas at level three the students are responsible for these three aspects. The work done in a Lernwerkstatt can be regarded as level three which is open inquiry.

Levels of Inquiry according to Bonnstetter (1998)	**Traditional Hands-on**	**Structured**	**Guided**	**Student Directed**	**Student Research**
Topic	Teacher	Teacher	Teacher	Teacher	Teacher/Student
Question	Teacher	Teacher	Teacher	Teacher/Student	Student
Materials	Teacher	Teacher	Teacher	Student	Student
Procedures/Design	Teacher	Teacher	Teacher/Student	Student	Student
Results/Analysis	Teacher	Teacher/Student	Student	Student	Student
Conclusion	Teacher	Student	Student	Student	Student
Level of Inquiry according to Abrams (2007)	**0** **Verification**	**1** **Structured**	**2** **Guided**	**3** **Open**	

Table 2: Assemblage of Abrams' (2007) and Bonnstetter's (1998) levels of inquiry

In Bonnstetter's (1998) description six elements in an inquiry process are mentioned. These are "topic", "question", "material", "procedures and design", "results and analysis" and "conclusions". Bonnstetter specifies five levels of inquiry, which can be related to the levels described previously.
Level zero matches Bonnstetter's "Traditional hands-on" where all elements are guided by the teacher. Level one and two are also called structured and guided. Inquiry of type three is divided into two types, "student directed" and "student research". At the type student-directed all elements except the topic are open to students; in "student-research" even the topic is chosen by students. Both types are common in Lernwerkstatt.
As previously mentioned, we wanted to find out which personal theories the heads of Lernwerkstatt have. Jarvis (1999, p. 145) wrote that *"personal theories consist of fully integrated knowledge that combines learning from doing and thinking about practice with learning from other information sources"*. Thus, the daily practice and the continuous reflection of the work the heads of Lernwerkstatt carry out are important.
To fathom the possibilities and potentials of Lernwerkstatt for pre-service teachers and to gain insight into the usage of open inquiry at pre-service teacher education the following research questions were posed: What are the specifications of a Lernwerkstatt? What goals do the heads of Lernwerkstatt at universities have for the work in their Lernwerkstatt in the context of pre-service teacher education? What is the expected impact of the Lernwerkstatt experience on pre-service teachers? Therefore, a selection of heads of Lernwerkstatt was interviewed.

METHODS

To understand the potentials and to identify the learning opportunities of a Lernwerkstatt an interview study was carried out. This qualitative approach was used to meet the objective of collecting and comparing the diverse perceptions of the interviewees.
Ten heads of Lernwerkstatt from Germany, Switzerland and Austria were selected for the interviews based on the following criteria: i) being head of a Lernwerkstatt at their respective universities, ii) conducting teacher education and professional development programs.
Expert interviews were made manual-aided with narrative elements (Meuser & Nagel, 1991). The manual contained requests like "Could you describe your Lernwerkstatt?" or "What do you think are the effects of the Lernwerkstatt courses you offer?" The interviews were conducted at the respective interviewee's Lernwerkstatt and took about an hour each. They were done between August 2009 and March 2010, anonymized and analyzed using qualitative content analysis according to Mayring (Flick, 2009; Mayring, 2008) to extract the personal theories of the interviewees concerning the three research questions. After extracting the personal theories their correlation to the relevant theoretical backgrounds were discussed within the working group. Those connections between the personal theories of the interviewees and the correlating theoretical backgrounds are shown in the results.

RESULTS

In the following three sections the three research questions are addressed. The extracted personal theories are connected to theoretical backgrounds underpinned by quotes from the interviews.

Specifications of a Lernwerkstatt

The results of the interviews show that the physical room of the Lernwerkstatt is considered to be important for an inquiry process. The purpose of the room is to create an atmosphere which triggers questions in the pre-service teachers' minds. One interviewee said: *"I think, it's the atmosphere of the room. [….] to create an atmosphere which initiates learning and* *communication"* (I1, 118) [1]. The *"atmosphere of the room"* is not only interpreted as the material environment (Fraser, Anderson, & Walberg, 1982), as a room with interesting objects, but as a complete learning environment. A learning environment contains many aspects. It is an arrangement of methods, techniques, materials and media (Reinmann & Mandl, 2006) contributing to the inviting and curious-making *"atmosphere"*. A learner-centered approach is used (Bransford, Brown, & Cocking, 1999) where the focus is on the learner with his/her previous knowledge, experience and interest.

The heads of Lernwerkstatt consider the objects in the Lernwerkstatt as central tools to trigger an inquiry process. The presented phenomena initiate investigations. A quote from an interviewee: *"That's basically the starting point, the amazement and wonderment. Then they [the pre-service teachers] carefully approach to a phenomenon […]"* (I3, 49). The corresponding theoretical background is the phenomenological approach. Buck (2006) writes that through interaction between the person and the object understanding is constituted. On behalf of the objects there is an emphasis on the perception through one's senses (Østergaard, Dahlin, & Hugo, 2008).

In a Lernwerkstatt it is central that the learners inquire a question of their own interest and take the complexity of a phenomenon with all its conditions into account. A community of practice is created among the pre-service teachers and the heads want to foster communication and reflexivity. An interviewee stressed: *"They [the pre-service teacher] are forced to let the others know about their learning path and to reflect it"* (I3, 25). All these previously mentioned conditions get in line with the theoretical background of situated learning (Bircher & Schmid, 2006; Gerstenmaier & Mandl, 1995; Lave & Wenger, 1991). That determines authenticity, complexity, social interactions, problem orientation, communication and reflexivity as significant to promote learning.

Goals of the heads of Lernwerkstatt for their work

The research question of an inquiry is often hard to find and hard to phrase. Also, the pre-service teachers are often not used to conduct an investigation and to reflect the methods they use. The abilities to conduct an inquiry like to *"identify questions"* or *"design and conduct scientific investigations"* (NRC, 2000, p. 19) which should be developed during teacher education as they were often not addressed in pre-service teachers own school-careers.
The interviewees wanted to emphasize on the necessity to learn how to do inquiry and how to pose a research question. One of them said: *"They [the pre-service teachers] have learnt to give answers. […] to phrase a question, that's not easy!"* (I6, 194).

Vital to the success of the students during open inquiry is how they are being scaffolded during their process. In the Lernwerkstatt, teachers often stay attentively in the background and support the learners when needed. To develop these competencies the pre-service teachers take the role of learners being scaffolded. More and more, they change their role: *"The pre-service teachers undertake a transformation process from learner […] to teacher who can scaffold students themselves"* (I3, 29). In the analysis of the interviews it appeared that the pre-service teachers have the possibility to do inquiry themselves and discuss that experience on a meta-level. But only one Lernwerkstatt was able to contribute the opportunity to work directly with students to the prospective teachers. All other heads of Lernwerkstatt have to refer the pre-service teachers to internships at schools to practice their scaffolding skills, but without supervision and reflection by the Lernwerkstatt educators. For the teacher educators it is important that the pre-service teachers experience scaffolding themselves and that they transfer the knowledge about scaffolding into their own teaching. The interviewees stated that the experience of open inquiry makes pre-service teachers more aware of difficulties in learning processes and heightens the appreciation for these processes. As the learners are responsible for their inquiry process a new teacher role is required (De Jong & Van der Valk, 2007; van der Valk & de Jong, 2009). Scaffolding can be provided in various ways e.g. by asking open questions or reflecting students' comments (Furtak, 2006, 2008; van Zee & Minstrell, 1997). In the literature about Lernwerkstatt the following ways of scaffolding are additionally highlighted: to appreciate the learner's way and to provide support, sources and materials when needed (Zocher, 2000).

An overall goal for the heads of Lernwerkstatt is to engage pre-service teachers in inquiry learning, showing them an additional teaching method and ways of how to provide the learning environment "Lernwerkstatt". The heads think that all these parts are necessary to implement open inquiry learning in school. The reported claims the heads of Lernwerkstatt have can also be found in the NCATE (National Council for Accreditation of Teacher Education) Standards as normative goals (2008, p. 70), for example: *"they [science teachers] understand multiple methods of inquiry and engage students in scientific inquiry …"*.
Additional normative goals for the heads of Lernwerkstatt are that their pre-service teachers gain personal experience and reflection competence as well as to be aware of their own biographical learning experience. *"They [the pre-service teachers] have to recognize the educational socialization they have experienced"* (I3, 25), an interviewee mentioned. That approach can be found in the German KMK Standards (2004). These standards determine the goals which have to be achieved by teacher education as well as recommendations how these goals could be attained e.g. by *"personal testing and reflection of concepts in role play, simulated or real lessons"* or *"analysis and reflection of the own biographical learning experiences"*(KMK, 2004, p. 6).

Impact of the Lernwerkstatt experience on pre-service teachers

"We [the heads of Lernwerkstatt] are working with creeds. We have not done empirical research" (I3, 26), one interviewee said. Another one mentioned in the interview: *"I hope so [that we have impact], but we haven't done any research projects"* (I2, 98). The teacher educators in the Lernwerkstatt refer only to personal experience and just a few cases from former pre-service teachers who came back to the Lernwerkstatt as teachers. It is assumed by the interviewees that pre-service teachers who have experienced learning in a Lernwerkstatt will use open inquiry in schools more frequently than pre-service teachers who did not have the opportunity to attend Lernwerkstatt courses. They criticize the missing empirical research themselves.

Summing up, the extracted personal theories of the heads of Lernwerkstatt correspond to five theoretical backgrounds. These are phenomenology, situated learning, learning environment, scaffolding and inquiry learning. The standards for pre-service teacher education were added as a normative frame.
Even if the heads of Lernwerkstatt do not explicitly mention those theoretical backgrounds in the interviews, they underlie implicitly the principles and goals of the courses in the Lernwerkstatt to support learning.

CONCLUSIONS AND IMPLICATIONS

During pre-service teacher education, prospective teachers should become familiar with the variety and scope of teaching and learning methods, which can be used at school. As inquiry learning gains importance in science education it has to be integrated into teacher education (Rocard et al., 2007). For pre-service teachers Lernwerkstatt seems to be a suitable option to

initiate a professional development process in the field of inquiry learning: gaining experience in doing open inquiry themselves, discussions within the community about the experience and reflection out of two perspectives, out of the learner's and of the teachers' point of view. All these activities help the pre-service teachers to implement scaffolding into their own teaching.
The prejudice about Lernwerkstatt that there is no theory behind it is widely spread. In fact there is little literature. So we connected the personal theories of the heads of Lernwerkstatt to existing theories about learning. Thus, theoretical backgrounds from other contexts can be consulted to establish a Lernwerkstatt.
Further empirical research focussing on the learning process and professional development of pre- and in-service teachers is conducted. In future conceptions of pre-service education programs enough time should be granted for one's own inquiry learning experience, reflection and the practice of scaffolding skills. The latter is profoundly underrepresented in a current Lernwerkstatt. Interviews with teachers about their Lernwerkstatt experiences and case studies of learners at Lernwerkstatt at different ages will be done to gather empirical evidence about the impact of doing open inquiry in a Lernwerkstatt on the professional development of pre- and in-service teachers.

[1] The number indicates the position in the transcript of the interview.

LEARNING TO IMPLEMENT SCHOOL EXPERIMENTS IN A BLENDED LEARNING APPROACH: AN EVALUATION STUDY

Thorid Rabe[1], Olaf Krey[1] and Franco Rau[1]

[1]University of Potsdam, Germany

Abstract: This paper reports about the redesign of a traditional course on school experiments in physics that is part of the teacher education program at the University of Potsdam. A blended learning approach was chosen to improve the course in the sense of (1) a stronger focus on aspects of pedagogical content knowledge related to experiments, (2) an increase of time on task, and (3) fostering communication processes. The face-to-face lab course existent before was combined with online activities implemented by means of a mixxt-community. The implementation of the blended learning scenario was accompanied by an evaluation study that aimed at surveying students` perception of their gains in competencies and of the communication processes related to the course. The results presented in this paper are based on data collected with a questionnaire consisting of scales on perceived increase in subject matter knowledge, in experimental competencies, in nature of science knowledge and in aspects of pedagogical content knowledge. Results indicate that students appreciate the course in total, because it facilitates increase of competencies in all facets that were surveyed by the questionnaire. Yet, at the same time, students rate the influence of the online activities as put into practice in this course as rather low. The time on task effect shows up to be relevant in particular for the acceptance of the online activities. Consequences for an improved blended learning design and further evaluation are discussed.

Keywords: blended learning, hybrid course, school experiments, teacher education, evaluation study

BACKGROUND, FRAMEWORK, PURPOSE

The University of Potsdam holds a strong tradition in physics teacher education. As an important part of their studies in physics education students have to take a course in which they learn to conduct and to stage school experiments in the domain of physics. Experiences with this course - being a mixture of seminar and laboratory work - were twofold, so far. On the one hand, students are enthusiastic and motivated while conducting the experiments. They usually increase their abilities in staging and conducting experiments indeed. On the other hand, the authors found students showing up unprepared and struggling with content knowledge in physics, which we assumed to be already understood by the students. Hence, students paid little attention to topics related to pedagogical content knowledge in the field of school experiments (PCK) (Shulman, 1986) and did not develop the competencies we intended.

For improvement a blended learning approach was chosen (Bonk & Graham, 2005), sometimes also referred to as a hybrid course (Garnham & Kaleta, 2002). By definition “Blended learning arrangements combine technology based learning with face-to-face learning” (Kerres and de Witt, 2003). General expectations associated with blended learning relate to the improvement of students’ learning outcome and of quality of teaching. Access to learning opportunities and flexibility of learning are supposed to be increased while costs are reduced (Graham 2005).

The intention for our course was more specific and threefold. We aspired (1) to increase students' time on task, (2) to establish a continuous learning process and (3) to give additional opportunities for communication about experiment related PCK. One of the competencies students should have developed as a result of the course was to give reasons, objectives and purposes for using a certain experiment in a specific classroom context. Evidently, these are reasonable objectives or even key competencies for future physics teachers which have received quite some research attention within the science education community (e.g. Hart et al., 2000; Jacobsen, 2008 and the review article Lavonen et al., 2004).

To support our objectives, we used a social community (www.mixxt.com) as a supplement to our lab classes which, obviously, required physical attendance. The structure of the resulting hybrid course is shown in figure 1. All online activities are marked with an asterisk (*). The face-to-face course continued to focus on practical aspects of preparing and staging experiments for school physics. Direct interaction between students as well as between students and instructors took place here. The online activities in preparation of the laboratory work consisted of tasks to be worked out by the students. E.g. the students had to report on relevant pupils' misconceptions in the content area, they had to specify learning goals related to their experiments and they were asked to exemplify one experiment in greater detail. Furthermore, students were encouraged to comment on the work of the others in the sense of a feedback culture. The instructors of the lab course were asked to give online feedback as well and to give advice for improvement of the work done.

It was pointed out to the students that the online activities played an important role in the preparation of the face-to-face course and the assessment at the end of course. Anyhow, participation was voluntary. See figure 2 for an exemplary screenshot taken from our mixxt community.

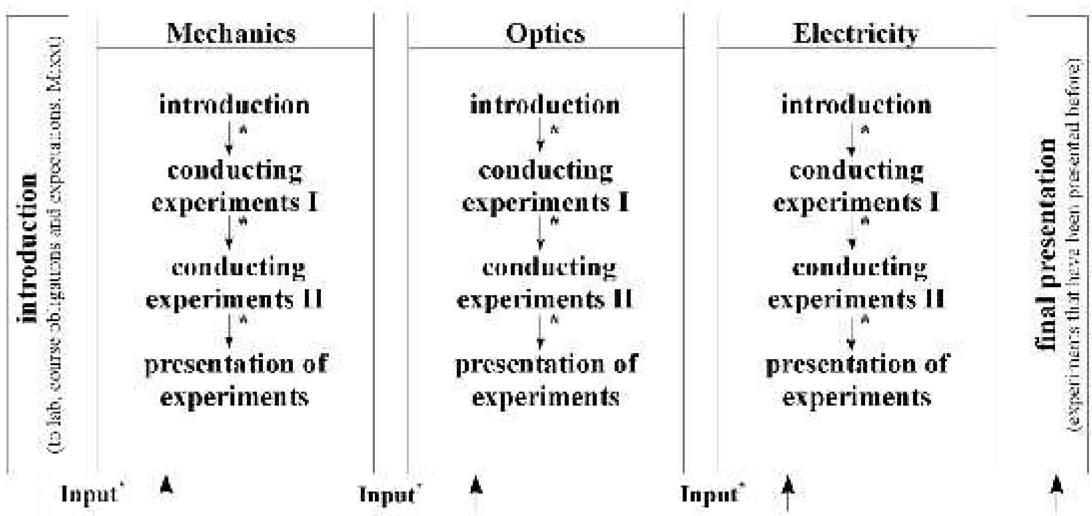

Figure 1: Structure of the blended learning scenario implemented in a lab course on school experiments in physics

The implementation of the blended learning scenario was accompanied by an evaluation study to gain an insight into the outcome of the design. Our interest - besides aspects of practicality or convenience of the hybrid format - concerned the students' acquisition of competencies. In particular, we wanted to learn about students' competencies in the subject matter and experimentation, their pedagogical content knowledge with reference to school experiments and knowledge of the nature of science as a result of the newly added online activities.

Due to the small number of students and reasons of fairness it was not possible to conduct a comparative study between a course with the blended learning structure and a course in the traditional format. Additionally, at that point of time no reliable instruments for direct measurement of the competencies mentioned before were available. Therefore, we decided to survey the increase of competencies as perceived by the students on the basis of overall course on one hand and cause by the online activities on the other hand.

Figure 2: Screenshot of the mixxt community

METHODS

A multi method approach was chosen to evaluate our course. Observations were conducted by one of the authors not directly involved in the teaching of the face-to-face course. Qualitative data from interviews with the teaching staff member and students were collected. Furthermore detailed protocols of students' and teachers' online activities are available (Rau et al., 2012).

Last but not least, a questionnaire including open ended questions and closed likert scale items (4-level, 0=no agreement, 1= little agreement, 2= some agreement, 3=full agreement) was employed. It is mainly the quantitative data resulting from this questionnaire that is presented and discussed in this paper. Scales were designed for our special evaluation interests as mentioned above. The factorial structure (main component extraction, promax rotation) and reliability of the chosen constructs was analysed and scales were identified. These scales were, then, used for analyses of correlation and variance. Our study included 19 teacher students (6 females), which explains why the final scales consist of very few items. As a first result, we were able to identify the scales shown in table 1 (together with their reliability coefficients (α), mean values (M) and standard deviations (SD). Moreover the questionnaire collected some personal data of the students and the estimated time they spent on online activities per week.

Scale	**caused by overall course**	**caused by online activities**
SMC perceived increase in subject matter competencies (4 items) *e.g. "I do understand the topics of physics."*	α=.74 M=2.12, SD=0.41	α=.80 M=.75, SD=0.54
ExpC perceived increase in experimental competencies (3 items) *e.g. "I can show specific phenomena by means of experiments."*	α=.66 M=1.81, SD=0.37	α=.95 M=0.36, SD=0.53
NoSK perceived increase in nature of science knowledge (3 items) *e.g. "I can explain the interrelation between models, experiments und laws in physics."*	α=.71 M=1.95, SD=0.51	α=.88 M=0.60, SD=0.61
PCK perceived increase in experiment related pedagogical content knowledge (4 items) *e.g. "I can anticipate problems in the realization of a certain experiment."*	α=.67 M=1.80, SD=0.55	α=.76 M=0.61, SD=0.48
CommPA perceived positive influence of mixxt on communication during physical attendance (5 items) *e.g. "The online activities fostered the interaction with the instructor."*	α=.75 M=1.13, SD=0.57	
CommOn perceived positive influence of mixxt on online communication (3 items) *"e.g. "The online activities encouraged the subject related interaction between students."*	α=.76 M=1.11, SD=0.64	
MixxtC competence using the mixxt community (4 items) *e.g. "The use of the online platform was easy to learn."*	α=.80 M=1.88, SD=0.63	

Table 1: Statistics of Scales

RESULTS

The handling of the mixxt community was not much of a problem for our students, as the mean value (see table 1, MixxtC) indicates. In contrast to our intention, the online activities were not perceived as very supportive for communication processes – neither online nor during the on-site time (see table 1, CommPA, CommOn).

The highest perceived increase in competencies was found for subject matter competencies (see table 1, SMC). This effect is independent from students' prior knowledge in experimental physics as an ANOVA (students have been assigned to a low, medium and high achieving group based on their grades in experimental physics) shows ($F(2;16)=1.06$, $p=.369$). This result can be explained with reference to what Riese (2010) found, namely that school related content knowledge is central for successful teaching but does not play an adequate role in physics teacher education. The perceived influence of the online activities on this increase in subject matter competencies is not a strong one, but it is existing independently from prior knowledge ($F=(2,16)=.68$, $p=.51$) (see table 1, SMC). A corresponding result can be found for the perceived increase in experimental competencies due to overall course ($F(2,16)=2.96$, $p=.081$) and due to the influence of mixxt ($F(2,16)=1.27$, $p=.308$) (table 1, ExpC).

Further, students perceived an increase of their NoS knowledge and - as we intended - also their experiment related pedagogical content knowledge (table 1, NoSK). Here again, the overall increase as well as the impact of the mixxt community activities are perceived, but not very strongly. As one would expect based on the literature (Kunter et al., 2007), subject matter proficiency (SMC), NoSK and PCK influence are highly correlated with each other, at least - and this is somewhat remarkable - for the part that was attributed to the online activities: $r(SMC,PCK)=.48^{*}$, $r(SMC, NoSK)=.71^{**}$. The same applies to reported gains in subject matter competencies and the experimental competencies: $r(SMC, ExpC)=.68^{**}$.

Of little surprise is the fact that the time on task – as estimated by the students themselves - provides a good predictor for the perceived increase in subject matter competencies. An ANOVA shows that the perceived increase is different (strong effect) for two contrast groups (split half): While students in group 1 investing $M=3.33$ hours per week ($SD=.78$) into course related activities on average perceived a reasonable increase ($M=1.94$ $SD=.32$), students in group 2 in average investing $M=6.57$ hours per week ($SD=2.94$) perceived a higher increase ($M=2.43$, $SD=.37$). This difference is statistically substantiated ($F(1;17)=9.15$, $p=.008^{**}$, $\eta^2=.35$). The same tendency can be found for the increase that was perceived due to online activities ($F(1;17)=7.67$, $p=.013^{**}$, $\eta^2=.31$). This also allows the conclusion that a positive effect of mixxt community activities is dependent on some dedication to that activity.

CONCLUSION

Students appreciate the course as being successful in offering learning opportunities and state a slight, but existent impact of online activities on the increase of competencies. Against our expectations, the influence of the blended learning approach was rather small or the questionnaire was not a commensurable instrument for measurement. Time on task was enhanced for at least some of the students. This leads us to generally following up the chosen approach. Still there is room and need for further improvement concerning the following aspects. We have to find ways of activating more students to take part in online activities to a full extent and on a deeper level of reflection. A stronger linkage between online activities and face-to-face communication could help to reach the full potential of a social community in the above described sense (continuity of the learning process and opportunity for communication). At first glance, qualitative data suggest that the (online) activity of the teacher trainer might be a crucial factor to foster students' activity as well. Therefore, it seems promising to train and brief the teacher trainers, to tie together the parts of the hybrid course and to support the continuity of online activities of students. Furthermore our instruments should be refined and supplemented e.g. by a scale measuring the motivational impact of mixxt activities. A design including control groups could help to objectify the subjectively perceived increase in competencies and direct methods of measurement of competency gains should be considered.

FUTURE PROSPECTS

The first insight into the implementation of a blended learning scenario in the teacher education program as presented in this paper is encouraging enough to follow up the chosen approach. Still, some lessons have been learned.

Concerning the technical realization we will substitute the mixxt community by wikis. We chose wikis, for substantial reasons as well as pragmatic ones. First of all our improved course design changes from voluntary documentation, reflection and discussion (for which the blog tool of mixxt.org was fitting well) to obligatory tasks that are constructed to prompt an in-depth study of certain aspects that play an important role in the process of preparing, conducting and reflecting a school experiment. The product of our students' learning effort is a wiki page which looks at a certain experiment from many perspectives and which has been improved and refined many times before it is finalized. The wiki based implementation also allows building up a database of physics school experiments. Finally the administrative effort (account setup, user and group management) is reduced.

To increase the students' engagement in online activities, and thereby, the time on task, a minimum of online activity was defined as a requirement for lab course attendance. Tasks for the students are specified and the format and complexity of the expected answers are clarified to the students. A joint project of all students in the course, the development of a database for school experiments in physics, is meant to increase the collaborative character of the online tasks. Future instructors of the lab course will be trained in attending the online activities in a supportive way. Here, an essential issue arises in that not only students' time on task is enlarged but also teachers' "time on work" is increased.

PRE-SERVICE SCIENCE TEACHERS' METACOGNITIVE AWARENESS ABOUT LAB INSTRUCTION AND THEIR COMPETENCY IN INQUIRY LAB DESIGN: THE CASE OF A LAB APPLICATIONS COURSE

Deniz Sarıbaş[1] and Ebru Z. Mugaloglu[2]
[1] Bogazici University
[2] Bogazici University

Abstract: The study investigated whether pre-service science teachers' metacognitive awareness about teaching science and lab instruction change throughout a laboratory applications course. The course aimed to improve pre-service science teachers' inquiry lab design. So, it was designed to consist of interactive lectures, discussions, micro-teaching practices, and writing reports of micro-teaching practices. 33 pre-service science teachers participated in the study. Data were gathered through pre- and post-course evaluation forms, instructional design instrument (ID), and student reports. The results showed that students developed their metacognitive awareness about science teaching and lab instruction by means of the improvement of their competence of inquiry lab design throughout the course.

Keywords: teacher training, inquiry lab design, metacognitive awareness

INTRODUCTİON

One of the aims of science education is to enable students to understand not only the scientific concepts but also the process of scientific inquiry (Shimoda, White & Frederiksen, 2002). Inquiry has long been addressed as a useful approach for effective science teaching (Ottander & Grelsson, 2006; Mugaloglu & Saribas, 2010). Yet, there is no single definition of inquiry. National Science Education Standards (NSES) defines three main types of inquiry, one of which is 'inquiry as teaching'. The present study focuses on inquiry as teaching, which refers to "the activities of students in which they develop knowledge and understandings of scientific ideas, as well as an understanding of how scientists study the natural world" (Anderson, 2002, p.23).

National Research Council (NRC, 2000, p10) states five features of inquiry. These are "(a) students engage in scientific questions which are posed by the students themselves or by the teachers, (b) students provide responses that prioritize evidence, (c) students propose explanations based on evidence, (d) students evaluate their proposed explanations in light of alternative explanations and accepted scientific knowledge, and (e) students communicate and justify their proposed explanations". Schwab (1962, cited in Settlage & Southerland, 2007) proposes a scale of three levels for the application of inquiry science teaching. In this scale, in Level 0, the lowest level of inquiry, the teacher has the complete control over instruction and the students are provided with all the components of inquiry, which include question, procedure, and the results of the investigation. In Level 1, the teacher gives students the problem of the investigation and explains the method of the experiment while the students are expected to find out the results of the experiment. In Level 2, the teacher gives the question and expects students to come up with their own procedure to solve the problem and conclude. In Level 3, the students have the full responsibility over the investigation and they are given none of these three components (Settlage & Southerland, 2007). Moreover, in recent years, metacognition has been considered as an important variable in learning science. Many researchers stated that metacognitive processes promoted meaningful learning, or learning with understanding (Gourgey, 1998; White & Mitchell, 1994; Rickey & Stacey, 2000; Saribas & Mugaloglu, in press). In a study conducted by Saribas & Bayram (2009) metacognitive development in chemistry lab improved pre-service science teachers' science process skills.

Within this frameworks, the aim of the present study was to investigate how pre-service science teachers' metacognitive awareness about lab instruction change with the development of their competence in inquiry lab design throughout a lab applications course. In the lab applications course, as literature pointed out the positive effects of collaboration (Anderson, 2002) on students' inquiry learning and their approach to inquiry teaching students worked collaboratively on their tasks and discussed every step of the process both in groups and in the whole class.

METHOD

Sample. 33 pre-service science teachers who took Laboratory Applications-I course in 2009-2010 fall semester participated in this study. The sample consisted of 9 male and 24 female students.

Assessment. All the participants were administered course evaluation forms (CEFs) and instructional design instrument (ID) before and after treatment. Course Evaluation Forms (CEFs) were prepared by the researchers to assess pre-service science teachers' metacognitive awareness about teaching science and science lab instruction. Students were administered pre-evaluation form before instruction and post-evaluation form after instruction. The two forms consisted of the same questions with different tenses in some questions. Instruction Design Instrument (ID) was prepared by the researchers to evaluate students' capability to design an inquiry-based lab instruction. An authentic problem was given in this instrument and the students were asked to design an inquiry lab instruction based on this problem (Attachment 1). Students' answers to this question were scored according to the rubric the researchers developed based on Schwab's inquiry levels (Table-1).

Table-1. Rubric for ID based on Schwab's model

	0	1	2	3	Score
Inquiry level	Structured	Problem and procedure are given	Only problem is given	None of the components are given	
Formulating introduction	No introduction	Unclear introduction	Clarifies aim or problem	Leads to inquiry	
Formulating procedure	Insufficient	Procedure is strictly given	Partially defined	Guide students to define their own procedure scientifically	
Formulating results and conclusion	Insufficient	Structured	Guides students to make conclusions (posing questions)	Guide students to make evidence based conclusions	

Procedure. The participants were exposed to an 11-week program including interactive lectures, discussions, micro-teaching experiences and reports of these experiences related to the design of inquiry-based lab instructions. The treatment was implemented in two different classes of students enrolled in fall semesters of the instructional years of 2009-2010 and 2010-2011 consecutively. Before treatment the students were administered pre-CEF and ID. Then students were divided into 6 groups in one semester and 5 groups in the other semester. Each of the groups included 3 or 4 students. In the first week of the treatment an interactive lecture about experiment and lab instruction were carried out. The focus was on experiment and types of lab work such as deductive, inductive, technical skills, science process skills lab and problem solving skills lab on this class hour. In the second week, lecture and discussions were carried out about inquiry and inquiry lab instruction on the basis of Schwab's levels of inquiry. The third week of the program focused on science process skills with some interactive activities. During these three weeks, the participants were responsible for designing a lab instruction on a predetermined environmental topic with their teammates. In their first micro teachings, students were free to design their lab instruction in any inquiry level. All the students prepared the reports of their microteachings including their individual reflections regarding the effectiveness of the instruction, and theories and methods discussed in previous lessons and used in the activities during micro-teachings. After micro-teaching experiences, the students responded ID in order to examine whether there was an improvement in their competence of lab instruction and the inquiry level they preferred to design in their instruction. Interactive lectures continued in the seventh and eighth weeks. In the seventh week, students were lectured about lab instruction styles such as expository, problem-based, discovery (guided-inquiry), and open-inquiry instructions. In the eighth week, the topics of cooperative and collaborative learning and peer review were discussed. Inquiry was the focal point of these two-week class hours. The students were responsible to design a lab instruction about any science topic. In the following two-weeks the participants presented their second micro-teachings collaboratively. During the course, after each micro-teaching, discussions were carried out about the effectiveness and the inquiry level of each presentation as well as lab instruction style, and the components of cooperative learning they used in the activities. Moreover, all participants prepared reports to reflect on their microteaching experiences. However, students' 2nd reports differed from their 1st reports in terms of assigning roles to each member of the groups for the purpose of implementing peer review in writing reports. One member of the groups was assigned as primary author, the other was assigned as editor, and the last one (or two) was/were assigned as technical reviewer. In the last three weeks the students presented their second lab instructions. After the 11-week program, all participants were administered post-CEF and ID.

RESULTS AND CONCLUSİON

Table-2 indicates that pre-service teachers had a significant improvement in terms of inquiry as a result of paired samples t-test.

Table-2: Results of inquiry design

	Paired Differences							
	Mean	Std. Deviation	Std.Error Mean	95 % Confidence Interval of the Difference			df	P
				Lower	Upper			
Pre-level – Post-level	1.67	0.92	0.16	-1.99	-.1.34	10.36	32	0.00
Pre-intro – Post-intro	2.12	1.22	0.21	-2.55	-1.69	10.00	32	0.00
Pre-procedure – Post-procedure	1.48	0.83	0.15	-1.78	-1.19	10.23	32	0.00
Pre-conclusion – Post-conclusion	1.64	1.08	0.19	-2.02	-1.25	8.67	32	0.00

Pre-inquiry –post-inquiry	6.91	2.45	0.43	-7.78	-6.04	16.17	32	0.00

Before the treatment, 48.5% of the participants referred to the need of improvement in knowledge and skills for designing and implementing lab instruction. After the treatment, all the participants addressed the knowledge and skills required for instructional design such as inquiry levels, method of instruction and/or science process skills. However, before the intervention they only emphasized a need for design in general terms. In other words, after the intervention participants' awareness of the need of knowledge and skills in designing and implementing lab instruction enhanced and varied throughout the study.

This result indicates a rise in metacognitive awareness of students in terms of teaching science and science laboratory instruction, after the treatment. It is consistent with the literature that points out the positive effect of inquiry laboratory for the development of metacognitive skills (Kipnis & Hofstein, 2008). National Research Council [NRC] (1996) suggests designing science curriculum emphasizing on inquiry skills. Mumba et al. (2007) advocates that syllabus and practical examinations for inquiry levels and inquiry skills are desirable for science educators. Further study, therefore, investigating pre-service science teachers' syllabus and assessments emphasizing inquiry levels and inquiry skills may have remarkable contributions to their inquiry lab design, their metacognitive skills as well as their approach to enhancing students' metacognitive and inquiry skills.

Attachment 1

Designing a science lab:

What is the best type of a soil to prevent flood?

Following the disaster in Istanbul, Ms Dogan, the science teacher of 8th graders, decided to encourage her students to find a way to prevent flood for an inquiry science lab. Below you will find her notes about definition of flood, her question and the materials in the lab. Please design the lab plan to complete her work:

Notes of Ms Doğan:
Definition of flood: It is an overflowing of water onto land.
Question: What is the best type of a soil to prevent flood?
Materials: Any glassware, graduated cylinder, different types of soil, stopper, Water, Stopwatch or any extra material

Abstract: Authenticity has recently become a popular term in science education. A study focusing on authenticity in the sense of making chemistry lessons resemble chemistry practice is carried out at the University of Cologne in the Institute of Chemical Education, where prospective chemistry teachers are trained. It has started in April 2010 and is an ongoing project. The short term aim is to challenge teacher students' pre-conceptions about characteristics of chemistry and chemical research. In the long term school practical-relevant elements of these characteristics are going to be embedded into teacher education courses. To achieve the short term aim a two-step approach was designed: at first elements to stimulate reflection on students' attitudes were identified. In a second step these elements were combined with an opportunity for teacher students to transform their reflected views of chemical research into a practical activity for pupils. In the long run these activities are going to be used to identify school practical-relevant elements in order to support pre-service teachers in designing authentic learning environments.

Keywords: Authenticity, learning environments, authentic chemistry lessons, pre-service teacher education

INTRODUCTION

Authenticity is a catch-word not only in everyday-life but it has recently become popular in the field of science education, without a common understanding of this term. There is a distinction between 'authentic' related to 'the students' lifeworld' and 'authentic' related to 'the practice of a scientific community' (Barab, Squire, & Dueber, 2000). The later is described by the principle of "making science learning better resemble science practice" (Edelson, 1998, p. 317). In chemistry teaching this refers to the chemical research and the people involved. The pupils should not only be confronted with parts of the investigation and become 'researchers' themselves, but they should also acquire knowledge about chemistry and science, which is not necessarily achieved by only conducting experiments (Abd-El-Khalick, Waters, & Le, 2008).

Authentic learning environments are often rooted in the concept of situated learning. Learning is associated with and depends on the context in which it occurs (Lave & Wenger, 1991). Therefore, the design of learning environments and the activities within gain importance.

Brown et al. argue that learning is also a process of enculturation and define “authentic activities […] as the ordinary practices of the culture” (Brown, Collins, & Duguid, 1989, p. 34) as a contrast to most school activities which lack context and thus cannot support structuring of students’ conceptions.

Related to these arguments is the concept of scientific literacy, a main goal of science education in school (Programme for International Student Assessment, 2004). Authentic activities in science lessons offer one possibility to promote this goal because they are “the only way [learners] gain access to the standpoint that enables practitioners to act meaningfully and purposefully” (Brown et al., 1989, p. 36).

In Germany the demand on scientific literacy can recently be found in educational standards (Kultusministerkonferenz, 2005). The competences are divided into subject knowledge, application of epistemological and methodological knowledge, communication and judgment (Schecker & Parchmann, 2007). These four aspects correspond to characteristics of chemistry (and scientific practice in general) such as content knowledge, thinking skills, scientific approach and social interaction (Chinn & Malhotra, 2002; Lee & Butler, 2003). Thus the claim for changing science lessons matches the call for more authentic learning environments.

Most of the examples in literature address pupils in school. The question arises whether pre-service teachers are able to meet the call for authenticity, i.e. are they prepared correspondingly during their education to put these examples into pratice? According to Lederman (Lederman, 1992) teachers’ conceptions constitute a necessary but not a sufficient condition for translation of these conceptions into school practice, thus this study focuses on prospective chemistry teachers at University level with two main research questions:

1. How can teacher students be stimulated to reflect about their pre-conceptions of chemistry and chemical research?

2. How can teacher students be enabled to create authentic learning environments?

PROJECT

Within the project, which is embedded into a theoretical framework representing the state of research, different aspects have to be considered (see Figure 1). There is the level of characteristics of chemistry and chemical research, about which students develop certain images before and during their studies, mostly without reflecting them. They are called pre-conceptions and one part of the project focuses on challenging these views and on analyzing how the original images change. This is going to be called post-conceptions. Characteristics of chemistry and research cannot be transformed one to one into school lessons (Edelson, 1998; Reiners, 2000); therefore practical-relevant elements shall be identified. Thus criteria of chemical research are condensed into practical-relevant elements, which in turn are going to be aligned if they still match the initial criteria.

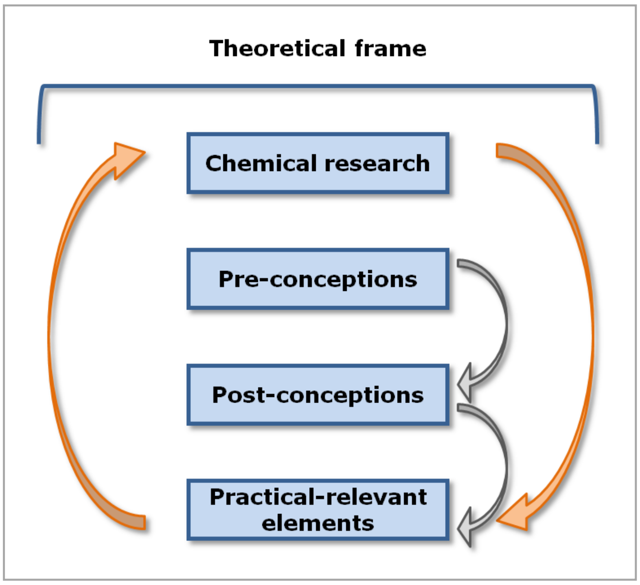

Figure 1: Overview project

To evaluate course elements that might be suitable to initiate teacher students' reflection about their views on chemistry (the step from pre- to post-conceptions), the course "Chemistry meets Chemistry Education" was designed in the summer semester 2010. The successful elements were maintained for the next course, in which they were combined with new course parts to approach the practical-relevant elements of chemistry and research.

This second course took place in the winter semester 2010/2011. 13 teacher students of chemistry (higher and lower secondary school, one for special education) participated, who were on average between the 7th and 8th semester. None of them participated in the first course. In the first part of the semester the students read and discussed various readings [1], which illustrated different aspects of chemistry and chemistry education. Another central part consisted of three talks of chemists given for the students, in which the scientists presented latest results in their field of expertise and gave an impression about their life as a chemist. The students were prepared for these talks by central scientific papers of the chemists and questions were gathered which the students wanted to ask. In the follow-up the talks were reflected and unclear issues were resolved. This part was to stimulate the students to reflect about their pre-conceptions. The discussion with other participants should help the students to critically contrast their own views with the ones of others. The first part ended up with formulating criteria of chemical research.

In the second part of the course the participants planned and conducted an out-of-school lab-day for a high-school class, in which a class came to our laboratories and were supervised by the students. With this lab day the students should convert the developed criteria into a practical activity. The students were free to choose the topic as well as the content and were only assisted by the course lecturers if necessary.

Research tools

For the study different research tools were used. Before the course the students filled out an open-ended questionnaire about characteristics of chemistry and chemical research in order to collect their pre-conceptions. During the semester a portfolio had to be written, thereby the students were free to use their own style. The only mandatory aspects were to reflect each lesson and voice their opinion as well as to make a purposeful reflection at the end in order to show how the initial image of chemistry and chemical research had changed. Approximately two months after the end of the course semi-structured interviews (Gläser & Laudel, 2009, p. 41) were conducted with each student, which were in parts related to the portfolio (for example to solve unclear issues), other parts were aspects of general interest for the study. The interviews were recorded and transliterated afterwards. Additionally the field notes taken by the researcher and the lab-day material developed by the students were used.

Analytical methods

To analyze the material a qualitative content analysis was used - the inductive category development according to Mayring (Mayring, 2008). A category system was created out of the obtained material and was guided by theory as well as by the research questions (Gläser & Laudel, 2009; Mayring & Gläser-Zikuda, 2008) [2].

From the questionnaires, portfolios and interviews individual profiles were generated in order to get insight in the learning process. Through the comparison of all profiles the first research question - if the course and its element were able to initiate reflection - was answered. Furthermore portfolios, interviews and field notes as well as the lab day material were used to find out how far the students have progressed on the way to a practical transformation, therewith contribute to answer the second research question. Especially the interviews served a double purpose: On the one hand they could reveal which conceptions were so concise that they still prevailed after some time. On the other hand they were used - together with field notes and lab day material - as a means of triangulation to validate the obtained results.

FINDINGS

First research question

All participants changed their pre-conceptions in the sense of correcting, broadening or concreting their previous views. The most common pre-conceptions (see Table 1) were *experiments and lab-work* as well as (*new) discoveries* and *progress*. The *picture of a chemist* as a (spectacled) male person who works alone in his laboratory was stated twice. In contrast to these common pre-conceptions three participants expressed more elaborated views (e.g. *no guaranteed results* or *using of these 'failed' experiments*), because they - unlike the rest of the group – had made prior experiences with (chemical) research.

Table 1: Most common named pre- and post-conceptions

Pre-conceptions	**Post-conceptions**	
	Category	
Experiments, lab-work (9)	Scientific approach	Experiments, lab-work (9)
New discoveries (5)		Discovery and creation (10)
		Various ways to do science (8)
		Experiments and theory (7)
	Epistemology	Theory and law (9)
		Chemistry is dynamic and evolves (5)
		Role of models (3)
		(Inter-)Subjectivity (6)
Image of a chemist (2)	Researcher personality	Creativity (11)
		Motivation and interest (8)
		Patience and frustration tolerance (6)
	Aims of chemistry	Objectivity (4)
Progress (4)		Progress (6)
		Pure and applied chemistry (7)
	Factors of influence	Ethical questions (7)
		Funding (6)
		Institutional conditions (5)
		Interdisciplinary approaches, collaborations (5)
		Not working alone (3)

The post-conceptions are divided into categories as described above (see Table 1). In the category 'scientific approach' - i.e. methods of science and how knowledge is obtained - the aspect *experiments* was still prevalent but it was complemented by several others. Also the students still stated *discovery*, but together with *creation*, for example the synthesis of new molecules. Especially by listening to the talks the participants realized that there are various ways to do science, for example they noticed that “one cannot plan everything. One has to use opportunities which arise […] there is no straight way for doing science” (Portfolio TA) [3].

Seven students explicitly connected *experiments* and *theory*, e.g. that “experiments are guided by theory” (Portfolio NA). This aspect is related to the category ‘epistemology’. Especially the terms *theory and law* were described more precisely at the end of the semester, for instance the development of scientific theories and therewith “chemistry research [as a] dynamic, advancing process” (Portfolio HS). Moreover the *role of models* was stated. Connected with these aspects is the factor of *(inter-)subjectivity* in science - for example the influence of the observer - which was a new issue for most of the students.

(Inter-)subjectivity is also associated with the category ‘researcher personality’. Due to the talks the students wrote and talked more about the ‘human’ aspects of research which play a role in doing science and being a chemist, such as *motivation and interest*, *patience and frustration tolerance* as well as *creativity*.

Though (inter-)subjectivity was realized as a part in science, the students also stated that science aims at being *objective* and “should communicate objective views” (Portfolio AZ). The aspects *progress* as well as *pure and applied chemistry* can also be included in the category ‘aims of chemistry/science’.

Other factors influencing research were mostly new to the participants, for example the aspects *ethical questions*, *funding* or *institutional conditions*. Connected with this category as well as with the category ‘scientific approach’ are *interdisciplinary approaches* and *collaborations* among scientists, which represented new aspects for some of the students. Additionally three people said that a chemist does *not work alone*; two of them were the ones who had initially imagined a chemist as “a little man alone in his laboratory [which] is definitely not true, you are not alone, only then scientific working is possible” (Portfolio LR).

According to these results the pre-service teachers were able to correct their prior conceptions through the course and its elements. The stimulated reflection was perceived as meaningful and important by the students: on the one hand for themselves as future teachers (8 students) and on the other hand for their future pupils (9). A lot of students expressed ideas about how to convey an image of chemistry into school lessons, e.g. by visits to research groups, which could demonstrate that chemistry is theoretical and practical work as well as social interaction. Furthermore they suggested using a historic approach to show the human aspects of chemistry as well as the development of theories.

Second research question

For the actual transformation of their post-conceptions into a practical activity for pupils - the out-of-school lab-day - the students chose the topic ‘A Chemical Winterday’. They developed five stations: ice-skating, heating pads, thermal conductivity, de-icing and separating processes. The students tried to implement some of the characteristics of science and chemistry in this day, e.g.:

- *Problem-solving* was used by some of the groups, for example in the separating process group the pupils had to separate an unknown (winterly) alloy with prior learned methods.
- *Self-reflection* was part of the thermal conductivity group, in which the pupils could learn something about the influence of the observer.
- *Hypothesis testing* and *environmental aspects* were implemented by the de-icing group; the pupils had to find out the best de-icer without being dangerous for the environments.

The students also experienced some difficulties during the planning of the lab-day. One of the problems was that the participants were unsure how to transform the criteria into a practical activity and how to start, i.e. to take one criterion which is considered important or interesting for the pupils and then try to find an adequate content or to approach this vice versa (7 students). Finding adequate experiments and creating appropriate learning materials turned out as another difficulty (6). Furthermore some of the participants stated that they have not made many experiences yet: on the one hand (5) they are lacking experiences with planning of lessons - since they are still at university - and on the other hand the students have not had many experiences with problem-solving or inquiry-based learning themselves (5). In the reflection one student wrote with regard to the questionnaire he/she filled out at the beginning of the course that he/she "presumably answered the questions like someone who does not study chemistry, probably because I have come in contact with chemistry during my studies, but not with the approach of a researcher" (Portfolio ET). The teacher students didn't necessarily relate this with the difficulties they felt during their planning, but this relation is worth to be considered in the future.

Despite the problems all the students appreciated the practical experience. As mentioned above a lot of them have not made a lot of practical experiences yet, so the preparation of the lab-day (the developing of learning material, designing and testing experiments and so forth) as well as the handling of (smaller groups of) pupils were perceived as a good testing situation and offered them support for their future as chemistry teachers:

> "I'm a bit anxious with pupils in the lab. To practice in a small group was the most valuable for me […]. It was good to be in the laboratory with pupils, to guide them and also this dialogue" (Interview AG)

CONCLUSIONS AND OUTLOOK

The course "Chemistry meets Chemistry Education" could successfully initiate reflection about the pre-conceptions teacher students have about chemistry and chemical research; all of the participants gained a more precise image about the subject they are studying. Moreover, this reflection is perceived as meaningful and important both for themselves as future teachers and for pupils as well. The transformation of the students' views into practical activities succeeds in part. As there are still some difficulties, the pre-service teachers need more support in designing authentic learning environments.

According to the overview of the project, the step from pre- to post-conceptions has been achieved with the two courses "Chemistry meets Chemistry Education". With the second course the way to identify practical-relevant elements is paved, but this step is not finished yet. The following step is going to be the alignment of the identified practical-relevant elements. As it turned out that the teacher students need more support in creating authentic learning environments, the long-term aim of this project is to develop a course for chemistry teacher education into which the practical-relevant elements are embedded, to give the students assistance with the transformation into practical activities.

The author thanks the DAAD for their financial support.

NOTES

1. For example: (Aikenhead, 2004; Hoffmann & Torrence, 1993; Johnstone, 2010; Olmsted III, 2010)

2. Since no Anglo-Saxon equivalent of Mayring's analysis exists, this is the author's translation of his approach. Mayring refers to grounded theory, but describes his analysis as more systematized. Criteria for selecting categories are to be defined before the analysis out of theoretical considerations in regard to the object and aim of the study. Next the data is worked through; new categories are constructed if a passage matches the established criteria. Several rounds might be necessary; thereafter a category system is the result, which can then be interpreted in regard to the research question.

PRE-SERVICE IRISH SCIENCE TEACHERS' MISCONCEPTIONS OF CHEMISTRY

Muireann Sheehan[1,2], Peter E. Childs[1], and Sarah Hayes[1]
[1]Department of Chemical and Environmental Sciences & National Centre for Excellence in Mathematics and Science Teaching and Learning, University of Limerick
[2]Irish Research Council for Science Engineering & Technology

Abstract: Science teachers in Ireland are prepared through either a concurrent model or a consecutive model of teacher training. The university involved in this study offers a concurrent model of science teacher training. Like many other pre-service science teachers and students of science worldwide, these students have many misconceptions in chemistry. It has been noted that this is, in the main, due to the abstract nature of the subject which requires learners to operate at a high cognitive level. The issue of misconceptions in chemistry is a significant issue for the quality of pre-service science teachers as they may leave their third level education without having ever had their misconceptions addressed. For an improvement in science education to occur teachers must be able to apply the findings of research into chemistry misconceptions, yet many pre-service chemistry teachers have numerous misconceptions themselves. The poor subject matter knowledge of these pre-service teachers is likely to lead to the transmission of misconceptions to their students. This study aims to investigate the number and type of chemistry misconceptions pre-service science teachers possess and whether these misconceptions are altered as they progress through their degree programme.

Keywords: Pre-service science teachers; Chemistry misconceptions; Science education; Subject Matter Knowledge

INTRODUCTION

The development of adequate subject matter knowledge (SMK) in pre-service teachers is one of the main goals of teacher education programmes. Teachers must have sufficient knowledge to be able to understand the underlying structures and organisation of a subject (Shulman 1986). Misconceptions in chemistry have been widely reported in international literature (Mulford and Robinson 2002; Tan and Taber 2009). They are known to be deeply rooted, resistant to change (Mulford and Robinson 2002) and their presence can interfere with new learning (Clement 1982). In order to address this problem, teachers must be prepared to directly address these misconceptions. Teachers' SMK must be sufficient such that teachers have a sound understanding of the subject and hold relatively few misconceptions themselves (Shulman 1986). The pedagogical content knowledge (PCK) of science teachers must also include knowledge of common misconceptions, which they may expect to find in their students, and strategies to reduce these misconceptions (Shulman 1986).

BACKGROUND & CONTEXT

Prospective science teachers in Ireland are prepared through either the concurrent or consecutive model. The concurrent model involves a four year degree programme in science, pedagogy and education. In the consecutive model, graduates of science complete a Postgraduate Diploma in Education. The university involved in this study offers a concurrent model of science teacher education. The mode of science instruction is a traditional lecture style, which has been found to emphasise lower order cognitive skills such as recall (Zoller 1993), and may result in inadequate pre-service teachers' SMK. The SMK of teachers has been shown to have a significant effect on teachers' ability to plan lessons, use appropriate representations and detect the misconceptions of their students. Teachers with under-developed SMK are more likely to include misconceptions in lesson plans and use inaccurate representations which reinforce these misconceptions (Hashweh 1987).

During the spring semester 2010, the results of an exploratory study involving third year pre-service teachers suggested that a number of chemistry misconceptions, particularly in the area of the particulate nature of matter (PNM), were present. A larger scale pilot study including pre-service teachers from all four years of study was then carried out. The research questions guiding this study were:

1. What chemistry misconceptions do these pre-service science teachers hold?
2. Is there a link between these misconceptions and gender, age, previous school experience of mathematics and chemistry or pre-service teachers' chosen course of study?
3. Are the misconceptions present in the first year of pre-service teachers' concurrent programme altered over the course of four years of formal study?

METHODOLOGY

Participants in this study were required to complete a pencil-and-paper instrument designed to assess for the presence of misconceptions in chemistry.

Table 1: List of Concepts & Questions included in the Instrument

Concept Area	Subtopic (where relevant)	Question No.	Concept(s) being tested	Source of Questions
Particulate Nature of Matter	Atomic Structure	Q7	Factors influencing ionisation energies	Taber (2003); Tan & Taber (2009)
	Chemical Formulae & Equations	Q5, Q6, Q11	Meaningful conversions from symbolic to microscopic	Mulford & Robinson (2002)
	Phase Change	Q3	Understanding of phase change	Yezierski & Birk (2006); Sheehan (2010)
	Conservation	Q4	Conservation of matter	Mulford & Robinson (2002)
	Composition of Matter	Q1, Q2	Microscopic nature matter	Sanger (2000); Mulford & Robinson (2002)
Mole Concept		Q8, Q9, Q10, Q12	The mole as a counting unit, use in stoichiometry and molar volumes	Sheehan (2010); Claesgens & Stacy (2003)
Chemical Bonding		Q13, Q14, Q15, Q16, Q20	Process and energetics of bonding, effect of bond type and structure of ionic compounds	Peterson & Treagust (1989); Mulford & Robinson (2002)
Equilibrium		Q17, Q18	Dynamic nature of equilibrium and the equilibrium constant	Krause *et al*. (2004); JCE website

Chemistry misconceptions and concepts related to the Leaving Certificate syllabus were identified based on the literature. The resulting instrument, described in Table 1, was composed of 23 questions and reviewed by experts. It was administered to each year group of pre-service teachers expected to receive a qualification to teach science. A response rate of 77% (212 participants) was achieved. Responses were analysed using PASW.

RESULTS

The percentage of first, second, third and fourth year pre-service teachers in each grade band are shown in Figure 1. The majority of pre-service teachers (>80%) achieved less than 40%.

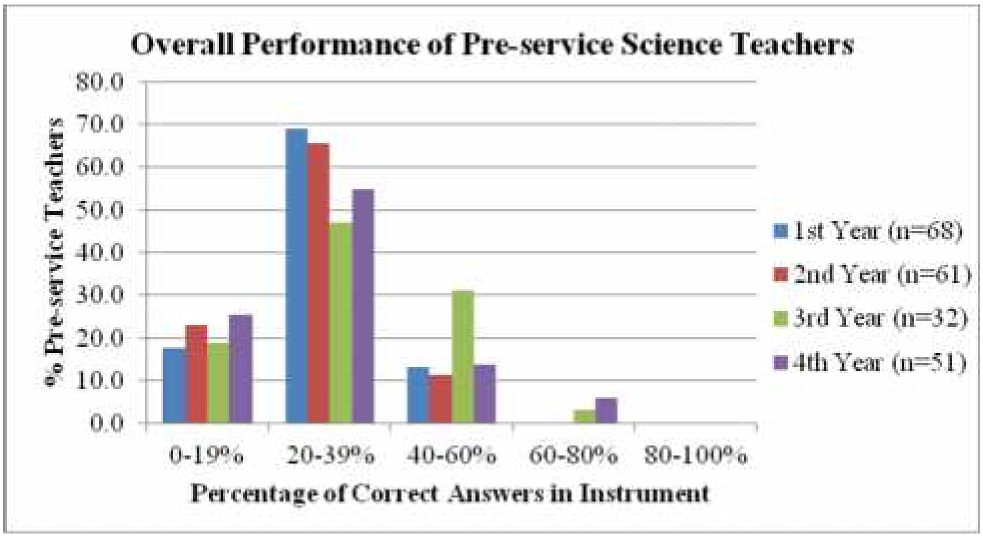

Figure 1: Performance of Pre-service Teachers in Instrument

Table 2 shows the average score for the entire sample group of 212 for each conceptual area included on the instrument. Pre-service science teachers displayed poor understanding of all the conceptual areas in the instrument, with PNM being the most poorly understood area.

Table 2: Breakdown of Mean Scores for Each Conceptual Area in Instrument

Concept Area	Questions	Average Score (n=212)	% of Sample not Attempting Section
Particulate Nature of Matter	Q1, Q2, Q3, Q4, Q5, Q6, Q7, Q11	28.2%	0
Stoichiometry	Q8, Q9, Q10, Q12	43.0%	0.5
Chemical Bonding	Q13, Q14, Q15, Q16, Q20	32.7%	1.4
Equilibrium	Q17, Q18	31.1%	0.9
All Areas		30.8%	0

In the pre-service teachers' responses, a number of significant factors emerged as having an effect on their performance. The year of study had no significant effect on their performance. A summary of the statistical tests performed may be found in Table 4. Figure 2 shows the performance of each year group for each question in the instrument. Nine questions were answered correctly by less 20% of the total cohort, with five questions related to PNM and two to chemical bonding. The highest number of misconceptions was in the PNM. Common misconceptions were a failure to conserve atoms (74.9%) and confusing the meaning of subscripts and coefficients (56.5%). Table 3 provides a list of the misconceptions.

Table 3: List of Specific Misconceptions found in more than 10% of Pre-service Teachers

Concept Area	Subtopic (where relevant)	Misconceptions Identified	% of Sample (N=212)
Particulate Nature of Matter	Atomic Structure	Use of Octet Rule analogy to explain differences in ionisation energies	42.0%
		Use of relation-based reasoning to explain differences in ionisation energies	34.4%
	Chemical Formulae & Equations	Confusing the meaning of coefficients and subscripts	56.5%
		A failure to conserve atoms or understand the role of a limiting reagent	74.9%
	Phase Change	A belief that a phase change from liquid to gas involves the breaking of covalent bonds	30.1%
	Conservation	Matter not conserved as gas weighs less or is less dense than solid	27.8%
	Composition of Matter	Attributing macroscopic properties such as density, melting point and structure to a single atom	52.4%
		Identifying all pure substances composed of elements as homogeneous mixtures	20.7%
		Identifying pure substances composed of compounds as heterogeneous mixtures	25.5%
		Identifying substances containing more than one element as compounds	30.2%
Stoichiometry	The Mole	The mass of a particle affects the number of particles in one mole of substance	31.1%
		The type of particles affects the number of particles in one mole of substance	10.4%
		12g of Carbon contains a mole of electrons	58.0%
		Unable to apply mole ratio to generic chemical equation	30.2%
	Volumetric Analysis	Belief that a solution of 1M contains molecular mass of substance in 1 L of water	19.8%
Chemical Bonding		Belief that an ionic bond involves the sharing of electrons	15.6%
		The electron pair is centrally located in a covalent bond	30.2%
		Breaking bonds releases energy	61.1%
		Ionic bonding is always stronger than covalent bonding	19.3%
		The presence of metallic bonds raises the boiling point of a substance	12.7%
		N_2H_4 is a resonance structure	15.6%
		Lone pairs can never exist on adjacent atoms	16.5%
		Nitrogen forms triple bonds when possible	26.9%
Equilibrium		Reactant concentration increases as equilibrium is established	28.8%
		Concentration fluctuates as equilibrium is established	20.3%
		Failure to understanding meaning of equilibrium constant	49.0%

Table 4: Significance of Relationships in the Study

Relationship being Tested	Statistical Test(s)	Result	Meaning
Gender & Overall Score on CMII	Independent Samples T-Test	t(210) = -4.43, p < 0.05	On average, male participants (M = 35.7, SE = 1.5) achieved higher scores than female participants (M = 28.1, SE = 0.96).
Age & Overall Score on CMII	Bivariate Correlation	r = 0.153, p < 0.05	Older pre-service teachers were found to achieve significantly higher scores.
Course of Study & Overall Score	One-Way ANOVA Hochberg Post-Hoc Test	F(5, 206)=8.29, p<0.05	The mean score for those studying '*Physical Sciences (ed)* (M = 44.2, SE = 2.6)' was significantly greater than those studying '*Biological Sciences with Chemistry Elective* (M = 29.4, SE = 1.8).
Leaving Certificate Chemistry Level & Overall Score	One-Way ANOVA Hochberg Post-Hoc Test	F(2, 171)=7.58, p<0.05	Pre-service teachers with higher level chemistry for the Leaving Certificate (M = 33.5, SE = 1.1) achieved higher scores than those that did not study chemistry for the Leaving Certificate (M = 25.5, SE = 1.7).
Leaving Certificate Mathematics Level and Overall Score	Independent Samples T-Test	t(204)= -3.30, p<0.05	Those that studied higher level mathematics (M = 33.4, SE = 1.2) for the Leaving Certificate achieved higher scores than those that studied ordinary level mathematics (M = 27.8, SE = 1.2).
Year of Study & Overall Score	One-Way ANOVA Gabriel Post-Hoc	F(3, 208)=1.79, p>0.05	Those in their fourth year of study achieved the same scores as those in their first, second and third years of study

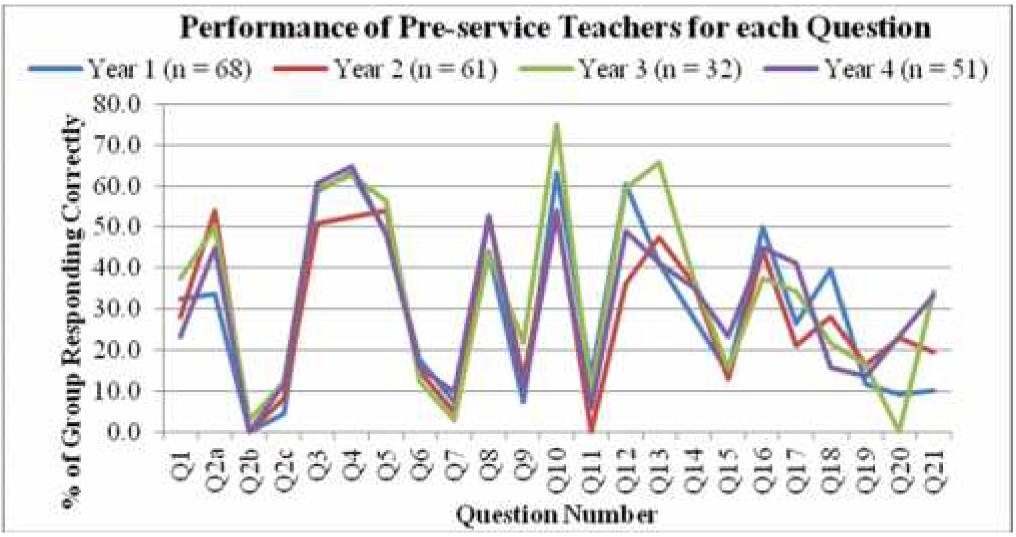

Figure 2: Breakdown of Performance of Pre-service Teachers for each Question

DISCUSSION

The number of misconceptions found among pre-service science teachers in the overall study was high with over 80% achieving less than 40% in the test instrument. The average overall score was 30.8%. Other studies, which have looked at the understanding of general chemistry concepts, have resulted in similar findings. Mulford and Robinson (2002) noted that the average score achieved by college students was 45.5%. In Ireland, Sheehan (2010) found that the majority of Junior Certificate (67.2%) and Leaving Certificate (63.8%) pupils achieved less than 40% in a chemistry concepts test. Direct comparison cannot be made between this study and our study, given that different instruments were used. However, both studies indicate that throughout secondary and tertiary level education in Ireland the number of misconceptions held by learners remains unacceptably high, and is little affected by additional years of study.

Gender, age and course of study had a significant impact on the number of misconceptions held: with pre-service teachers who were male, over twenty-one years of age and specialising in the physical sciences holding fewer misconceptions. The differences associated with these groups may be the result of higher cognitive levels. Male students at university level are more likely to operate at the formal operational level (Sheehan 2010) and Shayer and Adey (1981) noted a direct correlation between cognitive development and age. Those on the physical sciences course were more likely to have studied Higher Level mathematics for the Leaving Certificate and may have had a higher mathematical ability. A positive correlation has also been shown between mathematical ability and cognitive level (Sheehan 2010).

Pre-service science teachers demonstrated the poorest conceptual understanding in questions related to PNM (M=28.2%). Over 60% achieved less than 40% in this area. Yezierski and Birk (2006) note a similarly poor understanding of this conceptual area among college general chemistry students. The number of misconceptions held by pre-service teachers about PNM appear similar the number held by Junior and Leaving Certificate pupils (Sheehan 2010).

Possibly the most significant finding of this study is that there was no trend or significant relationship between the year of study and the number of misconceptions held by pre-service science teachers. In the vast majority of questions, there was also no relationship between the year of study and the responses selected. This suggests that neither the number nor type of misconception is significantly altered over the course of four years of the concurrent teacher training programme.

The results of this study indicate that the SMK of pre-service teachers in this particular university is weak. Participants demonstrated the poorest understanding in concepts related to the PNM which may be considered to be the foundation upon which all other conceptual areas in chemistry are built. The lack of understanding found in this fundamental area suggests that it is unlikely that these pre-service teachers understand the structure and organisation of their subject. As previously mentioned, a weak SMK and high levels of misconceptions may lead to these pre-service teachers creating lesson plans which include misconceptions, presenting inaccurate representations, reinforcing misconceptions and being unable to detect misconceptions among their pupils (Hashweh 1987).

CONCLUSIONS & IMPLICATIONS

The limitations of this study included its semi-longitudinal nature which merely provides a snapshot of the heterogeneous groups in each year of study. The results indicate that pre-service science teachers taking part in the study have unacceptably high levels of chemistry misconceptions across all years of study. These misconceptions are not reduced or altered in any significant way over the course of four years of study. This suggests that the concurrent science education programmes at this university are not successful in addressing pre-service teachers' misconceptions or deepening their understanding of chemistry concepts.

It is, therefore, producing teachers with weak SMK. Given their own lack of understanding of the subject, it seems unlikely that the PCK of these pre-service teachers is sufficient to allow them to identify and address the misconceptions of their students. The results of this study, in combination with the study performed by Sheehan (2010), suggest that the education system in Ireland is not successful in the reduction or alteration of chemistry misconceptions in learners. The concurrent programmes at this university would seem to be producing teachers that may only prove to worsen this state of affairs. This is a situation that clearly needs to be addressed.

STUDENT-TEACHERS' PARTICIPATION IN THE DEVELOPMENT OF DIGITAL STORIES FOR THE MOON AND THE TELESCOPE

Vasiliki Spiliotopoulou[1]
[1]General Department of Education, School of Pedagogical & Technological Education (ASPETE), Patras, Greece, spiliot@otenet.gr, vaspiliot@upatras.gr

Abstract: The focus of this paper is on how narrative forms of science learning material can be introduced in teacher education courses. Particularly the participation of two student-teachers in the development of two stories about the moon and the telescopes is explored. Historic and media information has been identified by one of the student-teachers in order to develop the storyboards of the scenario, while the technical and connective aspects of creating the digital form have been considered by the second. The development of the story scenario to narrate how the discovery of telescope and Galileo contributed to scientific development and how today the research about the moon has advanced was a demanding task. Evidence showed that the final learning digital products have been created through an intensive collaborative scheme in order to support student-teachers' difficulties at the conceptual and structural level. Implementation of the final products in classrooms reveals the potentiality of digital storytelling and also aspects that need to be considered for an effective science learning narration.

Keywords: Narrative forms of learning, Digital teaching stories, Nature & history of science, Collaborative teacher education, Authenticity in science teaching materials

INTRODUCTION

The quest of challenging environments for learning science is today an important goal of science education (Rocard et al, 2007), and is driven by the "sense of growing disparity between the science education provided in our schools and the needs and interests of the young people who will be our future citizens" (Millar & Osborne, 1998). The interwoven of science, pedagogy and technology (ICT) is desirable and is the focus of a number of research efforts (Web & Cox, 2004). In their extended review, Web & Cox conclude that reviewed research evidence suggests that teachers need to plan the focus of the assignment carefully and to provide appropriate materials that relate to the affordances of the multimedia composition experience and their teaching objectives. Doyle (2000) sees value in promoting versions of authenticity; he cautions that because school cannot be the real world, all content must be interpreted for teaching and the role of the teacher is to transform the subject matter into forms that represent authentic meaning to the child. One version of authenticity concerns the subject matter authenticity, in which the learning is designed to align with the work of professionals in the discipline (e.g. scientists) and for which the enemy is predigested versions of content in textbooks. Two ideas could enhance the development of authentic learning experiences: the invention of meaningful science learning stories and the utilization of digital storytelling. The inclusion of such ideas in teacher education and the case of two student-teachers' efforts to produce teaching multimedia material is described in this study.

RATIONALE

According to the Model of Educational Reconstruction (Duit, Gropengießer, & Kattmann, 2005), the content structure of a certain domain has to be transformed into a content structure *for* instruction, as the two structures are substantially different. Such a transformation today, however, can better take place taking into account pedagogical and technological considerations and utilities and teachers need to be prepared to act in such a frame. New technology can provide access to a wide range of information sources and is able to represent that information in a variety of forms - text, images & sound - for analysis and communication. Godfrey (2001) stresses the potential of ICT to present rich learning environments, allowing learners to adopt multiple perspectives on complex phenomena, to foster flexible knowledge construction in complex learning domains, and to cater for individual differences. Such representational forms of knowledge could also serve pedagogical approaches and curricular designs that integrate the sociohistorical understanding of science. The ‘stories’, which science tells about the material world and how it behaves, have made an enormous contribution to our culture (Fensham, 2001). Storytelling is considered as the original form of teaching (Pedersen, 1995).

Millar & Osborne (2000) argued that “science education should make much greater use of one of the world’s most powerful and pervasive ways of communicating ideas – the narrative form – by recognising that its central aim is to present a series of ‘explanatory stories’”, (p.2013). Although storytelling is not new, the idea of digital storytelling is new (Meadows, 2003). Within the last 10 years, digital cameras, editing software, authoring tools and electronic media outlets have encouraged teachers to utilize many more approaches and tools than ever before, to help students to construct their own knowledge and ideas to present and share them more effectively (Standley, 2003). One of these powerful approaches to multimedia production is digital storytelling. As the name implies, digital stories usually contain some mixture of computer-based images, text, recorded audio narration, video clips and/or music.

It is important for teachers to realize that stories of science told in classrooms could offer some understanding of where ideas exposed have come from. Moreover, benefits of using historical materials in primary science education have been recorded, while selecting and preparing historical source materials in digital format has been reported as a useful source of learning primary science (Kafai & Gilliland-Swetland, 2001). However, introducing such type of innovations in teacher education in order student-teachers to be able to develop their own materials is a demanding task. A ‘lesson study’ model (Hart, Alston & Murata, 2011) offers a possible model for teacher education. It places teacher at the center of the professional activity with their interest and a desire to better understand student learning based on their own teaching activities. Two distinct features characterize this model: lesson study has a research lesson and lesson study is collaborative. These ideas have been applied in two different teacher education courses. The study of student-teachers’ participation in the development and implementation of narrative learning materials was one of the goals of the efforts reported in this study. In this context the following research questions are posed: How can student-teachers be enhanced in participating in collaborative activities for the developmental and implementation of learning material? What does collaboration mean in such a frame? What kind of materials can be produced and which are their characteristics?

METHODOLOGY

The present research effort takes place in two different contexts of prospective teacher education contexts, the structure and philosophy of which follows a “design research” approach (Wood and Berry, 2003). It is also based on the ‘lesson study’ model (Hart, Alston & Murata, 2011). It also draws on Jaworsky’ s (2003) theoretical framework, which can be applied to analyse research projects involving multilayered research into teaching and teaching development in order to understand better the processes and practices involved, and the impact and outcomes of the research. The units of analysis are aspects and actions of the collaborative team that consists of two student-teachers and the educator/researcher. The focus is mainly on how two student-teachers' of different courses organized and taught by the educator/researcher, developed while working their final assignments on the development of teaching material on a topic concerned the moon, the scientists and the telescope. The first was a primary education student-teacher (Diana), who was involved in the project for a year, part of her degree thesis and after having attended a science education course for a semester. She designed and applied a detailed teaching intervention in a primary classroom. The second was a graduate of Informatics (Gregory), who attended a yearlong teacher education course, and simultaneously was part time teacher of basic ideas of informatics in primary education. He participated mainly in the production of digital teaching materials using the software Microsoft Photo Story 3 and he tried the final products with his primary students. Diaries of the meetings, the electronic communication, material collected and final products of this collaboration, videos and reports of the implementation in classrooms are the data of this study.

RESULTS

Student-teachers' involvement

The two student-teachers were enthusiastic while working on the project; they had a productive collaboration and worked hard. Two goals were initially posed for their work: to create a narration for the moon and the telescope and to utilize multimodal representational forms for the storytelling. The epistemic goal was, through their own involvement in the creation of teaching material and lessons, the development of students' awareness of the ways people have gained knowledge about the moon, of the value of instruments like the telescope and of how scientific knowledge and research methods changed over the time.

The main idea was the development of narrations for revealing the value of the invention of a scientific tool like telescope to primary students of 6^{th} grade. Historic persons' inventions, the role played by the sociohistorical environment, the real facts of science development are considered ideas that can attract and help students to appreciate the old and new approaches in the research about the moon. The actual adoption of these ideas by the student-teachers cannot be considered as given. Diana started to work on producing teaching material for the moon:

- She reviewed students' ideas about the astronomical concepts.
- She herself was informed and learned more about the science of the moon and produced a body of core concepts related to the primary teaching of moon.
- She studied appropriate bibliography and became aware of using history of science with students and of epistemic goals.
- She identified historical material both textual and visual.
- She finally tried to prepare a scenario for the moon and the telescope, and to present the narration in a PowerPoint form (the storyboard).

This storyboard would function as the basis board for the final digital narration. Diana was skeptical for the appropriateness of historical materials for primary students. Although she collected a number of interesting historic electronic materials, she was unable to understand their meaning and met difficulties in designing any form of narration. At this phase, the support of the educator was crucial in order the scenario to be produced.

Gregory developed the digital photo stories giving emphasis on artistic features selected successfully the music background and the narration of the story added his own images altering sometimes the desired meanings by emphasizing his choices, which aimed more the grace of narration than the revelation of the actual historical and conceptual aspects of the subject to be taught. Gregory, based on the already produced scenarios, developed the digital photo stories giving emphasis on technical and artistic features.

The two student-teachers cooperated in both the development of the video and the evaluation of classroom implementation. They both admitted how difficult but valuable the process of developing narrative teaching materials and digital Photo Stories is. Throughout this collaborative activity student-teachers expressed feelings initially of weakness to complete this task and to apply in classrooms, but finally satisfaction with the results and a degree of awareness of what such a digital teaching material means. All three participants of the lesson study team gained valuable experience throughout the lesson study collaboration and also during the classroom implementation.

Products

The initial plan was to produce one narrative teaching story. Through collaboration during the lesson study the initial narration broke finally to two scenarios and subsequently two storyboards have been produced. These were the basis for the development of the two final digital products, the videos. Parts of the created storyboards are presented in figures 1 and 2. The first story (fig. 1) describes the bombardment of the moon at 2009 and the discovery of water ice at the lunar South Pole. It ends by saying that at the old times people used other ways to learn about moon.

Fig. 1 The first scenario: the beginning of the storyboard

The second story narrates the invention of telescope, the role of scientists of this era and particularly of Galileo and the social obstacles he met when stated his arguments (fig. 2). It ends by stating that Galileo's ideas had been finally accepted and established in Newton's era. Scenes of Galileo's demonstration of the telescope to the senate and the Doge and later of his prosecution by the Inquisition are also involved.

Initial options during the process of scenario development have reconsidered and changed by the team. For example, instead of the astronaut of the last scene in Figure 1, a piece of information found by Diana, a young scientist in normal clothes sat in his lab desk was presented, while his words for the experiment were narrated. The young scientist's portrait and explanations had been found by Gregory after educators' suggestion to cross-check the details of the experimental procedure of NASA. This change was decided in order to highlight that scientists today are everyday people working on a specific scientific plan which includes a carefully designed bombardment of the moon, but also analysis of the vapor clouds guided from a computer lab in NASA.

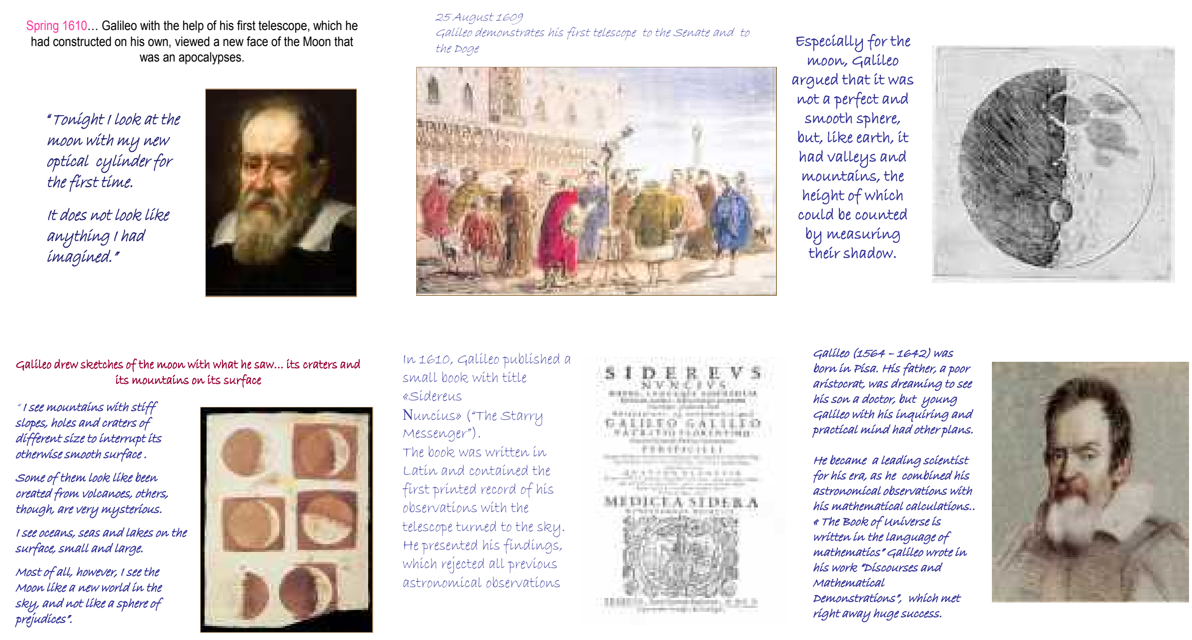

Fig. 2 The second scenario: Galileo episode

Classroom Implementation

The implementation of videos in primary classrooms by the student-teachers provided evidence of their function with the students, and offered to student-teachers the chance to integrate their lesson study experience. It, also, revealed how secondary narrative features of the stories attracted students' attention unintentionally.

Diana organized a lesson in a sixth grade classroom based on the two videos. An intervention with a number of tasks for the students before and after the play of the video was designed. 16 students participated in the intervention that lasted two hours. The analysis of data collected during the teaching implementation provided evidence of positive outcomes in many ways. Videos stimulated students' interest, supported their understanding of the content and context of the presented conceptual field and developed their awareness of how science develops and scientists work. Students' responses revealed a shift in the way they talked about the moon and the scientists from a general level to more specific issues, which the videos included. For example, more students talked after they attended the videos for the moon as satellite, the mission of LCross, the mountains and the valleys on the moon. They also talked more specifically for the telescopes and Galileo's life and role, while all of them referred the existence of water on the moon, fact that only few students knew at the beginning. Gregory used the videos in a freer way, but he also reported positive outcomes in terms of students' response to this experience similar to Diana's findings.

During the second scenario, where the story's duration was longer, students' interest and attention appeared to be decreased towards the end of the story. It seems that the balance in the use of historical details is crucial. It is worth mentioning the fact, that secondary narrative tricky features of the stories, like a reference to strange figures (one scene with the shape of the rabbit on the surface of the moon) that people many years ago believed to see at the moon affected students' perceptions.

Collaborative actions

Analysing the collaborative experience during the lesson study a number of actions have been identified: *actions between two members*, *common actions*. In terms of actions between two, we can distinguish between *querying actions* and *co-working in pairs*, while in terms of common actions we can distinguish *team work/decision making* and *sharing experiences*. For example, when Diana sent a mail to the educator asking how to proceed, it is a collaborative action between two and is characterized as a querying action. When Diana or Gregory communicated with the educator or between themselves to work together, this is characterize as working in pairs. Meetings with all three members of the team is meant to be a common action and when the discussion was around the story and its unfoldment, this is considered as team work/decision making. Finally, attending Diana's lesson and discussing about the students' understanding is considered as a common action with sharing experiences.

CONCLUSIONS

Aspects like authenticity, nature and history of science, narration of science stories, digital storytelling are important and challenging ideas to be involved in teacher education courses of science education and educational technology. These seem to obtain meaning and be possible only when student-teachers participate in projects aiming to develop innovative teaching materials that can be created through collaborative process. The lesson study model incorporates aspects like the development of research lesson, where teachers plan and implement the teaching materials like being researchers themselves. Another aspect is related to the fact that participants work both independently and collaboratively. It can be concluded that the particular factors of the student lesson cycle provided greater opportunity for the student-teachers to increase their knowledge for developing teaching innovative materials, for planning and implementing teaching interventions.

Our experiences working in the lesson study team show that student-teachers are able to initiate a lesson inquiry, by collecting information or by using technological tools, but they meet difficulties in building meaningful stories of the scientific endeavor, both at the conceptual and the technical levels. They are able to recognize the value of such narrations, but they feel uncertain with the inclusion of such teaching stories in classroom implementation. Collaborative approaches, between students and educators in the context of teacher education courses, offer valuable experiences to all participants and also opportunities for interesting and meaningful learning materials to be produced.

Four important factors have been identified and can be suggested as crucial for the production of the narrations and the teaching videos:

- the information and materials collected (real stories, visual representations, authentic sources),
- the development of the script scenario in order to attain the teaching goals, especially the epistemic ones,
- the selection and synthesis of the textual, visual and audio elements during the construction of the digital Photo Story, and
- the balance between images, narration, textual information on images and time spent in each screen.

Science stories help to frame the discourses of the school science classroom and different types of science stories told in science textbooks present implicit notions about the nature of science to teachers and students (Milne, 1998). The production of digital narrations is a complex task, but offers freedom to the designers to create a science story that will be 'politically correct' (Milne, 1998). This means that the contribution of people in science is presented more fairly and the interaction between science and society is examined critically giving the sense that they construct each other, as it happens in the second video produced in this study. Teachers need to be aware of the power of stories, and in producing meaningful stories collaborative schemes of work, like the lesson study, have a crucial role to play in teacher education and teacher development.

[1, 2, 3] National & Kapodistrian University of Athens,
Faculty of Primary Education, Department of Physical Science, Technology and Environmental Studies

Abstract: This study refers to distinguishing conceptual profiles in pre-service teachers' predictions and/or explanations about acid rain interaction with the natural environment. The way pre-service teachers make deductions about, and explain natural environment affection by acid rain is used as a case study topic in order to evaluate prospective teachers' ability to use scientific discourse when explaining environmental problems. In the course of a didactical intervention pre-service teachers were given the chance to interact with models of systems belonging to different scales through research-based-developed tools. The predictions and/or explanations pre-service teachers gave to the acid rain /environment interaction problem before, during and after the intervention were analyzed and five characteristic conceptual profiles were established.

Keywords: conceptual profile change, pre-service teachers, acid rain

INTRODUCTION

This study refers to distinguishing conceptual profiles in pre-service teachers' (students) predictions-explanations about acid rain interaction with the natural environment.
The study is based on a social constructivist perspective on learning (Leach & Scott 2005) according to which, science (as well as school science) is a social language providing the experts (or the students) with ways of talking and thinking about the natural world and thus explaining it. Students come to the science class bringing their own "everyday language" that has evolved in their social lives through normal day-to-day interactions. Students' acquisition of science language in the class plane is intermediated by their everyday language. Based on this social constructivist tradition, Mortimer (1995) suggested the notion of 'conceptual profile'. That means that it is possible for students to use different ways of thinking in different domains and that a new concept does not necessarily replace previous and alternative ideas, but everyday and scientific concepts may coexist. Even in the science classroom there may exist different conceptual profiles that indicate a movement from everyday language to school science language and these profiles have emerged as the result of the dialogue between these two languages. All these characteristic ways of thinking are "acceptable" and depict the conceptual evolution in the classroom. Research has shown that although high school students and in-service teachers try to use school science language to explain environmental phenomena they fail to reach scientific discourse which construes the world as consisting of hierarchically organized systems at different scales (Gunckel *et al* 2010, Anderson 2010). This study occurred in the context of a broader research studying how pre-service teachers explain

environmental phenomena using different scales' systems and processes. More precisely, the research questions are: a) what are the pre-service teachers' conceptual profiles when interpreting the acid rain natural environment interaction? b) How do these conceptual profiles change when interacting with models and systems belonging to multiple different scales?

METHODOLOGY

The acidic water / weathered bedrock reaction beneath soil is of great importance in the way acid rain affects the natural environment. Calcareous soil neutralizes acidity thus protecting surface waters and terrestrial ecosystems while siliceous soils are gradually acidified, in a time frame of some decades, and similarly are the waters on such watersheds (JCE, 2003).
In the context of a three - stage didactical intervention (fig. 1), pre-service teachers tried acid rain / environment interaction on different scales. They tried different materials' -mainly siliceous and calcareous- interactions with acids and bases in the wet lab. They tried "building" ecosystems lying on different bedrocks and zoomed into the micro-scale systems through research-based-developed educational software in the computer lab.
The didactical intervention was implemented in the academic year 2008-2009 with 59 pre-service teachers attending an environmental course at a pedagogical University in Greece. Pre-service teachers' descriptions and explanations about the acid rain / environment interaction recorded in worksheets during the didactical intervention, as well as pre and post tests filled in before and after the intervention formed the data source of the research (fig. 1).

Fig 1: Data collection during intervention

Initially, the data were analyzed and quantified regarding the way students use different scales' processes by means of a system of three categories ("Levels", "Kind of Change", "Effects on Ecosystems") containing 4-6 subcategories each. This analysis results have been presented elsewhere (Stoumpa *et al*, 2010).
Afterwards, the whole of the quantified data was revised in order to distinguish if characteristic patterns can be derived in the way pre-service teachers understand and describe the phenomenon. That is, if it is possible to distinguish different conceptual profiles that are

characteristic and representative for the pre-service teachers' conceptual evolution through their contact with different scales' systems during the didactical intervention. Thus, the overall category "Phenomenon Description" was constructed. As it is plausible, pre-service teachers change conceptual profile during the didactical intervention and even after it. Finally, five characteristic types of "Phenomenon Description" (conceptual profiles) were established as described below:

Descriptions that correctly explain how acidic water reaction with stones and minerals beneath soil prevents (or isn't enough to prevent) acidification, thus protecting aquatic and terrestrial ecosystems abiotic factors and life. This profile is called "**Sound Integrated**".

Descriptions that relate the reaction with the protection of ecosystems laying on calcareous subsoil, with some errors however, either because pre-service teachers think that this protection isn't universal, for example that this effect is restricted to aquatic ecosystems, or because they fail to provide a complete description of the reaction. This profile is called "**Transitional**".

Descriptions relating the strong acidic water / calcareous stones reaction to strong ecosystems erosion and/or considering that ecosystems lying on siliceous rocks are durable due to rocks durability. This profile is called "**Pragmatic**".

Descriptions that successfully describe the acid rain effects on ecosystems biota on calcareous (or siliceous) subsoil, but without any reference to the acidic water/weathered rocks and minerals reaction. This profile is called "**Phenomenistic**" which in Greek means clinging on just what is obvious.

Descriptions that fail to approach the phenomenon both in describing the ecosystems evolution under acidic affection and in giving a description of acid / stone reaction, even a simplistic one. These descriptions are characterized as "**Inadequate**".

RESULTS

In the following chart (fig 2) the conceptual profiles that where identified before, during and after the intervention are depicted:

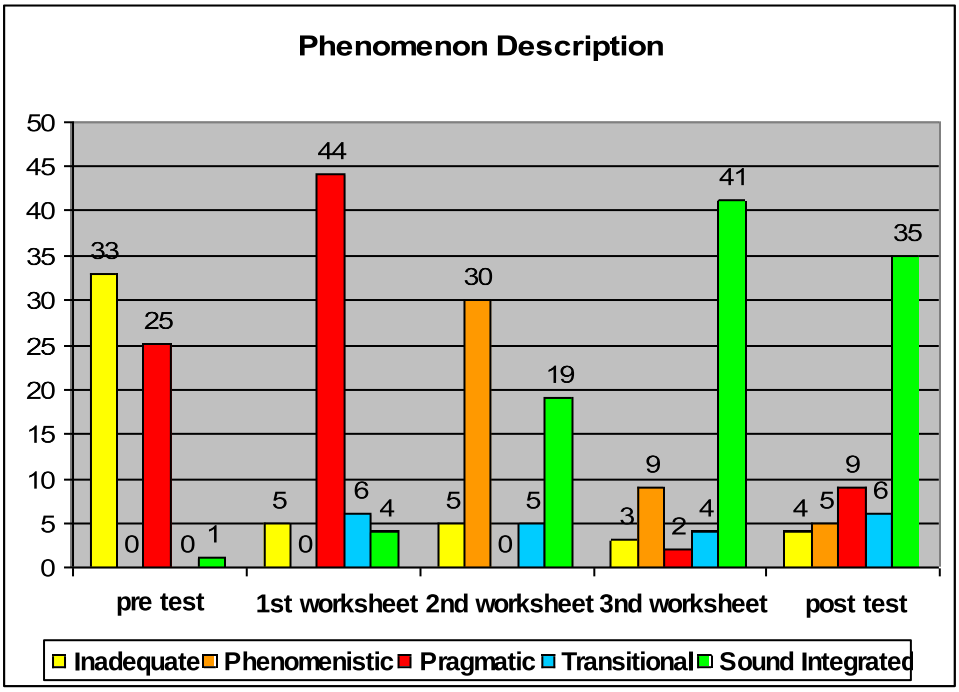

Fig 2: "Phenomenon Description": Conceptual profiles evolution during the intervention

Initially (in the pre test) pre-service teachers tended to consider the environmental phenomenon either making “Inadequate” predictions either superficially applying their knowledge about macroscopic phenomena to whole ecosystems (strong stone affection means strong ecosystem erosion).

In the wet lab (“macroscopic” approach) the pre-service teachers observed the damage acids cause to calcareous materials as well as the durability of siliceous ones. This encouraged them to deduce damage for ecosystems when the bedrock is calcareous, and durability when the bedrock is siliceous. So, the majority of them moved to “Pragmatic” descriptions. It is worth mentioning that all of them had taken measures about pH changes and recorded them down on their worksheets. However, a small but not insignificant proportion of them went ahead to “Transitional” and “Sound Integrated” descriptions.

The “Large scale” approach in the computer lab (ecosystems’ supervision) led a significant percentage of them to move on to “Transitional” and “Sound Integrated” descriptions in which pre-service teachers realized how the reaction protects soil and water by neutralizing acidity, thus protecting biota. However, those who failed to see this “good” side of the reaction preferred to ignore it and gave “Phenomenistic” descriptions.

The introduction of the microscopic (atomic/molecular) systems in the third stage of the intervention led the majority of them to “correctly” and more sophisticatedly understand the macroscopic processes and helped them to “successfully” relate the chemical interactions with abiotic factors’ properties and the corresponding consequences to the aquatic and terrestrial life.

CONCLUSION AND IMPLICATIONS

As the results suggest, the microscopic approach, in the end of the didactic intervention, significantly enhances the ability of pre-service teachers to form "Sound Integrated" descriptions and explanations of the problem they studied. However, it was the whole approaching in different scales that helped them to gradually familiarize with the science language. So, student -teachers' interaction with natural world phenomena on different scales, significantly contributes to their ability to understand the development of phenomena taking place in too large time and space scales to be directly observed, as well as the mechanisms underlying and explaining this development.

Since environmental phenomena and problems are large-scale ones, it seems that such interactions can enhance environmental science literacy, meaning the pre-service teachers’ ability to understand and participate in evidence-based discussions of environmental problems or critical environmental issues. Consequently, it is recommended that teaching materials be created, giving pre-service teachers the chance to try and observe systems that are too small or too large to be directly perceived. This is in accordance with other researchers’ studies suggesting that research-based didactic material and didactic interventions development may lead to students reaching (or at least approaching) scientific discourse reasoning (Anderson 2010, Mohan & Anderson 2009).

Abstract: Establishing conceptual relationships among macroscopic, symbolic, and microscopic levels is important in chemistry teaching and learning. The aim of this study was to investigate how pre-service chemistry teachers use macroscopic, symbolic, and microscopic levels and how they integrate teaching strategies with these three levels while teaching particulate nature of matter. Also, their opinions on the importance of using these levels in their instructions were examined. Eight pre-service chemistry teachers participated in this study. Three open-ended questions were administered to all participants at the beginning of practice teaching course. Then, three participants were interviewed to deeply analyze their responses. Written responses of question-2 were analyzed by researchers independently, then they came together to reach a consensus. Results indicated that pre-service chemistry teachers mostly preferred to use lecturing method at each level of chemistry in their instructions. Moreover, most of them had difficulties in using all levels and integrating these levels into teaching methods/strategies while teaching particulate nature of matter. However, they thought that using these three levels while teaching chemistry concepts is important in order to enhance student meaningful learning. Thus, teacher education programs should emphasize macroscopic, symbolic and microscopic levels, interactions among them, and how to use these levels in chemistry teaching.

Keywords: particulate nature of matter, macroscopic, symbolic, microscopic, pre-service chemistry teachers

BACKGROUND, FRAMEWORK, RATIONALE, AND PURPOSE

Establishing conceptual relationships among levels, which are macroscopic, symbolic, and microscopic, is important in order for students to meaningfully understand chemistry (Hinton & Nakhleh, 1999; Johnstone, 1993). The macroscopic level of chemistry is related to the observable phenomena such as burning a candle and color change. The symbolic level is represented using pictorial, algebraic, physical, and computational shapes. At the microscopic level, burning candle becomes a chemical process and carbon atoms of the wax react with oxygen molecules in the air, thus carbon dioxide molecules are produced (Hinton & Nakhleh, 1999; Wu, 2003).

Research studies revealed that students could not correctly explain chemical concepts using these three levels (Hinton & Nakhleh, 1999; Pozo, 2001). Especially, they have difficulties in understanding chemistry topics at the symbolic and microscopic levels (Tsai, 1999; Wu, 2003). Reasons of these difficulties might be their poor understanding of nature of particles (Ben-Zvi, Eylon, & Silberstein, 1986; Williamson & Abraham, 1995), their incomplete or inappropriate mental models (Harrison & Treagust, 1996), and their poor connections between school science and real life experiences (Osborne & Freyberg, 1985 as cited in Wu, 2003).

Recent studies on pre-service teachers' use of three levels have shown that pre-service teachers explain chemistry concepts using the macroscopic level, but they cannot use the symbolic and microscopic levels during instruction. Moreover, they cannot create connection among these levels (Lee, 1999; Pozo, 2001). The purpose of this study was to investigate how pre-service chemistry teachers (PCTs) use the macroscopic, symbolic and microscopic levels, and how they integrate teaching strategies into these three levels while instructing particulate nature of matter (PNM). In addition, their opinions on the importance of using these three levels in their instructions were examined. Research questions of this study were as follows:

1. How do PCTs use the macroscopic, symbolic and microscopic levels while instructing PNM?
2. How do PCTs integrate teaching strategies into the macroscopic, symbolic and microscopic levels while instructing PNM?
3. What are the pre-service teachers' opinions on the importance of using the macroscopic, symbolic, and microscopic levels in their instructions?

METHODS

Eight PCTs, 3 males and 5 females, enrolled in practice teaching course in a state university in Turkey participated in the study. Three open-ended questions were administered to all participants at the beginning of the semester. Suggestions of six experts in chemistry education were taken into consideration about the open-ended questions. After the first teaching practice of participants in the high school and university, three of them were voluntarily interviewed to deeply analyze their responses to questions. Interviews were tape-recorded and lasted approximately 45 minutes. As this study investigated pre-service teachers' understanding on PNM at all levels, researchers examined only question-2 which is presented below:

"You are supposed to teach PNM to your students by integrating the macroscopic, symbolic and microscopic levels into your instruction.

a) What kind of teaching method(s)/strategies would you use? How would you design your instruction? Why?
b) How would you teach PNM concepts at each level?
c) Do you think that this kind of instruction affects your students' understanding of PNM? Why?"

Qualitative content analysis method (Creswell, 2009) was used to analyze the data. Firstly, responses of participants were analyzed independently by each researcher. During the data analysis, the researchers took into consideration whether the participants integrate the macroscopic, symbolic and microscopic levels into their instruction, and which teaching methods/strategies they used while teaching PNM at each level. Moreover, the researchers categorized the participants' opinions on the effects of using levels in their instructions on students' understanding of PNM. Then, all researchers came together and discussed the answers to reach a consensus on the answers. The names of the participants were coded as from PCT-1 to PCT-8. PCT-1, PCT-2, and PCT-3 were also interviewees in this study.

RESULTS

Results of the study indicated that PCTs mostly prefer to use lecturing method at each level of chemistry in their instructions. To teach PNM at the macroscopic level, PCT-2 and PCT-4 stated that they would use lecturing. For instance, in her written response, PCT-2 claimed that she would give chemical bonding concept at the macroscopic level as; *"I will give firstly the definition of these two concepts (ionic and covalent bonding) and I will give examples from daily life."* In the interview, she also confirmed to use lecturing at this level as; *"At macroscopic level I'll state what ionic compound is. I'll use lecturing and I'll relate sodium chloride with daily life by saying that sodium chloride is table salt."* On the other hand, PCT-1 used demonstration while teaching the void structure of matter at the macroscopic level and stated it as;

"I use demonstration to explain the void structure of matter. For example: ethyl alcohol + water mixture. Before the demonstration; I ask students what they expect to see or at the end of the demonstration I want them make prediction for the aim of experiment."

She also confirmed same ideas in the interview. PCT-6 preferred to use analogy. He stated that *"For the macroscopic level, I would use analogy which will make the understanding of the topic easy for students, for example, I may use solar system analogy for the Bohr's atomic model."* Other four participants did not state any method and also they did not teach PNM at this level.

To teach PNM at the symbolic level, PCT-1, PCT-2 and PCT-4 stated that they would use lecturing. For instance, PCT-4 explained how she would give the instruction on the topic of compounds at the symbolic level as; *"to present the symbolic form of the molecule, I would draw on the board that one oxygen atom is bonded to two hydrogen atoms to form a water molecule."* PCT-2 also wrote that *"I will write examples to the board by using Lewis dot structure and symbols of elements. I will show the occurrence of ionic and covalent bonding with correct arrows."* However, in the interview, she claimed that she would enrich her lecturing using questions related to the formation of compounds from elements to make students more active. Other five participants did not state any method for teaching PNM at this level. Although PCT-3 did not propose any method in her written responses, in the interview, she stated that she would use lecturing while teaching PNM at the symbolic level.

PCT-1, PCT-2 and PCT-4 stated that they would use lecturing to teach PNM at the microscopic level. All of them mentioned that they would use videos and animations to show the structure of matter at the microscopic level during their lecture. For instance, in her written response, PCT-2 explained this situation on the topic of ionic and covalent bonding as; *"I will use an animation or video to show students what happens at the microscopic level while these bonding occur."* Moreover, in the interview, she claimed that she would support lecturing using analogy to teach ionic bonding at the microscopic level. Other five participants did not state any method for teaching PNM at this level. Although PCT-3 did not mention any method in her written responses, in the interview, she claimed that she would use lecturing by supporting animations while teaching at the microscopic level as *"Just saying an element loses or gains electron while forming a compound is not sufficient. We also need to use animations to make them understand the concepts at the microscopic level."*

Finally, in both written responses and interview, most PCTs thought that teaching chemistry topics at three levels is important. They claimed that this kind of instruction has powerful effects on student learning since it provides meaningful learning by making concepts more concrete. In addition, they thought that it helps students to visualize the concepts; therefore, students do not try to memorize concepts. Moreover, they stated that learning in the microscopic level prevents students having misconceptions on the concepts. One of the participants explained this situation as following: *"When the instruction doesn't include the microscopic level, students could not be able to understand the concepts so these concepts should be made concrete."*

CONCLUSIONS AND IMPLICATIONS

The PCTs participated in the study thought that it was important to use these three levels while teaching chemistry concepts in order to enhance student meaningful learning. However, they had difficulties in using all levels and integrating these levels into teaching methods/ strategies while teaching PNM. Several studies in the literature support the findings of the present study (Bektas, Tuysuz, Ekiz, Uzuntiryaki, 2010; Pozo, 2001). Although all participants had taken teaching method courses, they only preferred lecturing method for all levels in their instructions. It is recommended that teacher education programs should emphasize the practical lessons regarding integration of levels to the different teaching methods in chemistry. Moreover, if representations and explanations at the symbolic, microscopic, and macroscopic levels are emphasized during teacher training programs, pre-service teachers' difficulties in using three levels can be overcome.

CHEMISTRY TEACHERS' CONTENT KNOWLEDGE AND ITS CORRELATION TO PEDAGOGICAL CONTENT KNOWLEDGE

Oliver Tepner[1] *and Sabrina Dollny*[1]

[1]Faculty of Chemistry, Chemistry Education, University of Duisburg-Essen, Germany

Abstract: Although the construct of professional knowledge has been gained in center stage of educational research, content knowledge as one of the main aspects is only marginally handled. While in many studies teachers' content knowledge and its relation to other teacher characteristics are not based on a direct measurement, a large-scale test instrument for quantifying chemistry teachers' content knowledge has been developed. The development of test items in a multiple choice single select format was based on a theoretical model which considers different types of knowledge, different topics, and curricular classifications. Besides evaluation of content knowledge, a scale for describing teachers' pedagogical content knowledge was used and background information was collected. This study's sample includes 166 teachers of different school types (basic general education, extensive general education, intensified general education, and comprehensive school) which show significant differences both in content knowledge and in pedagogical content knowledge. This procedure allows for revealing aspects influencing teachers' content knowledge and information about the correlation between content knowledge and pedagogical content knowledge. Furthermore presented results serve as a basis for discussion on teacher's content knowledge needed in school, which is one main topic of the overarching symposium.

Keywords: content knowledge, large-scale test instrument, chemistry, professional knowledge, pedagogical content knowledge

BACKGROUND, FRAMEWORK, AND PURPOSE

Teachers' professional knowledge is widely believed to be one of the most important factors contributing to high quality instruction (Abell, 2007; Peterson, Carpenter, & Fennema, 1989). Recent literature conceptualizes professional knowledge in three dimensions, mainly based on Shulman's ideas for teacher education (Baumert et al., 2010; Shulman, 1987; Shulman, 1986): Pedagogical knowledge (PK), content knowledge (CK), and pedagogical content knowledge (PCK). These are seen as common facets that should be taken into account when considering competencies a good teacher should possess (Baumert et al., 2010; Grossman, 1990). This study focuses on subject-specific knowledge of chemistry teachers.

On a subject-related level, CK is conceptualized as knowledge of subject-specific facts and concepts (Cochran & Jones, 1998). Referring to Baumert et al. (2010), content knowledge is formed as a result of curriculum-related work; that is, the designing and structuring of subject-specific contents for teaching. It embodies much more than just factual, everyday knowledge based on academic fundamentals (Shulman, 1987). CK could be seen as one of four components of subject matter knowledge (content, substantive, syntactic knowledge, and beliefs), which includes some aspects of PCK, already (Cochran & Jones, 1998). PCK can be described as a fusion of pedagogical and content knowledge. This type of knowledge is used to transform a specific topic into teachable content (Shulman, 1987). When exploring teachers' CK, it can be useful to take aspects of PCK into account, additionally, because an explicit connection between PCK and CK in a teacher's knowledge base is assumed.

RATIONALE

The study is based on recent data gathered from mathematics teachers showing that teachers teaching 11-18 year olds hold more secure subject-specific CK and demonstrate better quality PCK than those teaching 11-16 year olds alone (Krauss et al., 2008). We were prompted to investigate if such findings hold true for chemistry teachers. In Germany, the locus for our study, a "non-intense", non-academic general education ends at 16. There are two school types, in which only this lower secondary age group is taught: basic general education (Hauptschule), and extensive general education (Realschule). In other secondary schools, a more intense, academic, general education is offered that ends at age 18 (intensified general education, Gymnasium) and at age 19 (comprehensive school, Gesamtschule) with the award of an entrance qualification for university. In general, CK can be assumed to be a precondition for PCK (Baumert et al., 2010).

Our study therefore investigates:

1. What differences in chemistry CK are observed in teachers teaching at intensified and non-intensified level?

2. To what extent does the quality of chemistry PCK correlate with teachers' chemistry CK?"

METHODS

166 chemistry teachers working at non-intensified level (basic general education, extensive general education), and intensified level (intensified general education, and comprehensive school) were asked to complete questionnaires probing their chemistry CK and PCK. Both were constructed in a paper/pencil form and required approximately 45 minutes to complete.

The questionnaires were based on content themes centered on 'structure of atoms and the periodic table', 'chemical bonding', and 'chemical reactions using acids and bases'. Because these topics are part of the curriculum of all middle schools, every chemistry teacher could reasonably be expected to hold CK and PCK about them.

The underpinning theoretical structure is provided by three axes (Tepner et al., submitted). Two, themes (listed above) and knowledge, are common to both tests. The knowledge axis comprises declarative, procedural, and conditional knowledge (Paris, Lipson, & Wixson, 1983). While declarative knowledge mainly refers to facts, procedural knowledge takes operations and processes into account. Conditional knowledge is knowledge about reasons and conditions under which some aspects are relevant for instruction. The third axis differs between the two questionnaires. In the CK questionnaire, the third axis was curricular classifications, which permitted grading of questions by level of difficulty suitable for students aged 12-15 (grades 7-9), aged 16-18 (grades 10-12) and first years of undergraduate study (aged 18-21). In the PCK questionnaire, the third axis was called "facets" (Park & Oliver, 2008), and comprised models, experiments, and students' preconceptions, all of which are assumed to be relevant for effective instruction (van Driel, Verloop, & de Vos, 1998).

Both questionnaires were developed in cooperation with teachers working in school for several years and lecturers in chemistry education at university. The CK questionnaire comprises 25 multiple choice/single select items (four answer alternatives per item), and the

PCK questionnaire includes 19 items. The reliability of both tests is good (CK: $\alpha = .83$, PCK: $\alpha = .83$).

RESULTS

The first research question deals with differences between teachers of intensified education and teachers of non-intensified education regarding their chemistry content knowledge. Revealed CK differences are significant ($t(164) = -10.79$; $p < .001$; $d = 2.02$ [Figure 1]).

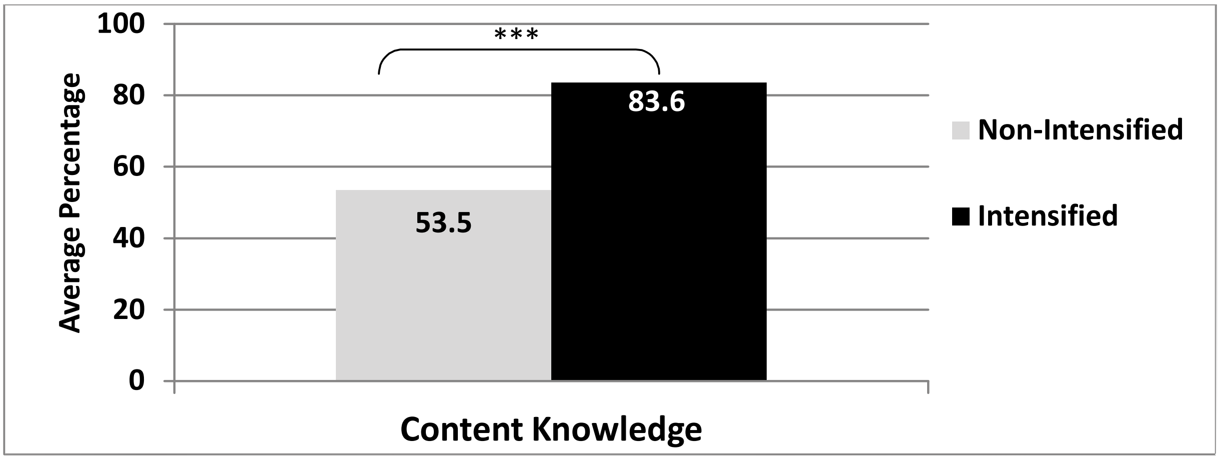

Figure 1. Differences between teachers of different school levels regarding their CK

Furthermore, CK has a substantial influence on developing PCK. While differences between teachers of intensified education and non-intensified education in terms of PCK are significant ($t(32.94) = -3.68$; $p = .001$; $d = 1.01$ [Figure 2]), PCK differences decrease when CK is incorporated as a covariate.

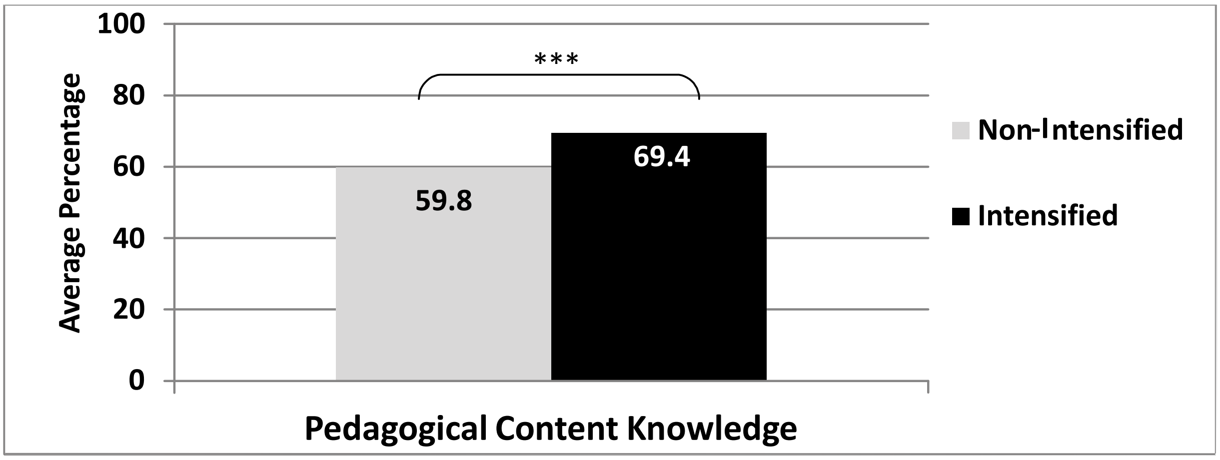

Figure 2. Differences between teachers of different school levels regarding their PCK

If CK is taken into account the ANOVA reveals a non-significant difference between intensified and non-intensified teachers' PCK ($F(1,163) = 1.413$; $p = .236$ [Figure 3].

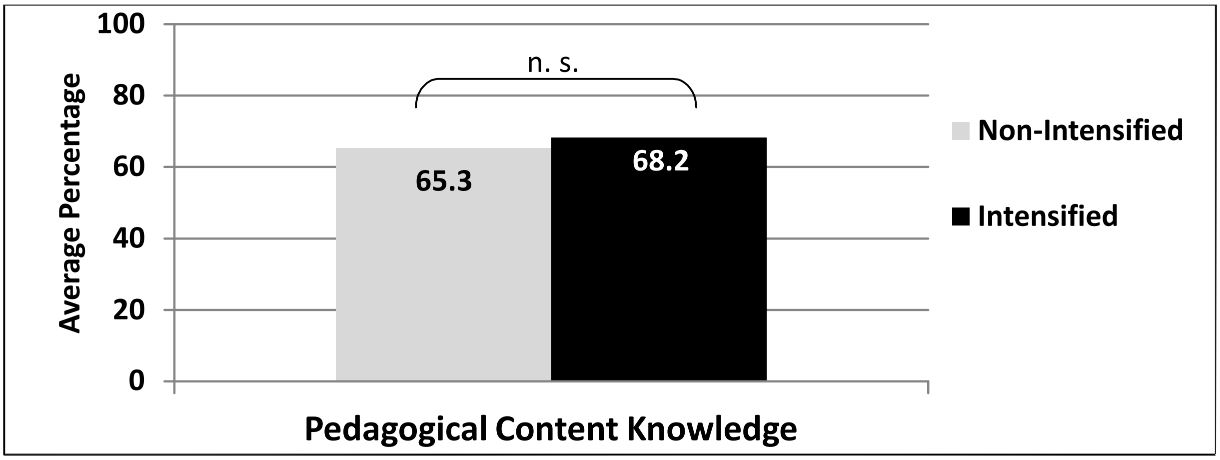

Figure 3. Differences between teachers of different school levels regarding their PCK (Covariate: CK)

The second research question analyses correlations between CK and PCK. Analysing the sample, a significant correlation of $r = .36$ ($p < .001$) between CK and PCK questionnaire can be found [Figure 4]: for example, teachers scoring highly on the CK questionnaire regarding a specific topic know much more about students' misconceptions in the same topic than those with poor quality CK, who scored badly in this aspect of the questionnaire. Nevertheless, the intensified education teachers' correlation between CK and PCK ($r = .17$; $p = .047$) is weaker than that of the non-intensified teachers ($r = .44$; $p = .018$).

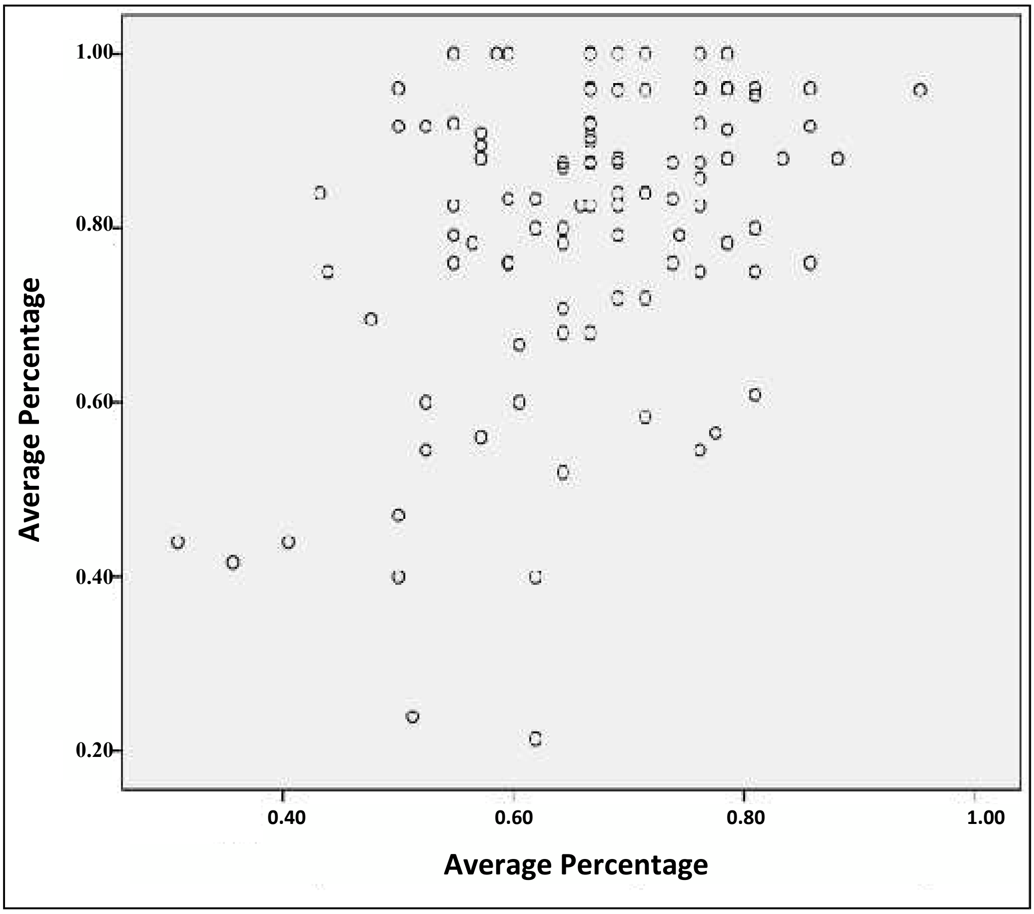

Figure 4. Correlation between CK and PCK

CONCLUSIONS AND IMPLICATIONS

Our evidence suggests that teachers' chemistry content knowledge varies according to the type of school in which they work. Teachers not using all tested levels of CK in school everyday show limited chemistry CK. The development of CK is more related to school type than development of PCK. This might be a matter of learning opportunities in studies, and a matter of requirements in daily work.

Correlation between CK and PCK is sufficiently high to be interpreted as substantial, but low enough to see CK and PCK as different dimensions (Baumert et al., 2010). The moderate but significant correlation corroborates the increasingly accepted belief that possession of good CK is a pre-condition for developing high quality PCK. Higher correlation between CK and PCK at non-intensified level might give a hint that a basic level of CK is a prerequisite for developing PCK, while a high CK does not affect a high PCK to the same extent. So CK might be a necessary but no sufficient condition for developing PCK. Additionally, intensified education teachers seem to be specialists either in PCK or in CK.

As a consequence, focusing on school type specific knowledge aspects should be reconsidered and CK immediately interlinked with PCK as it is needed in school. Discussion about this topic will contribute to recent international debate about the relative effectiveness of school- and university-based teacher education programs (Dreyer, Lesser, & Scheder, 2011; Ohle, 2010).

From a methodological point of view, this study reveals that developing and effectively using a large-scale test instrument for measuring chemistry teachers' CK and PCK is possible. The assessment tool could be used for further research on chemistry teachers' knowledge and serve as an adequate feedback tool for teachers.

PRE-SERVICE TEACHER TRAINING: BRIDGING THE GAP BETWEEN SCIENCE AND TECHNOLOGY

Maike Tesch[1]
[1]Institute for Mathematics and Physics Education (IDMP), Leibniz University of Hanover, Germany

Abstract: The paper presents results of an intervention and pre-post-study with pre-service physics teacher students. As science and technology are crucial for the wellbeing of industrial countries a lot of programmes have been started by governments to improve science and technology education. Governments intend to increase the number of students and former academic workers. In the German educational system there is a clear distinction between science and technology education. While science is established at schools technology is not. There is a strong need for reintegrating technology education into the curricula of schools. We understand our work as a bottom-up-initiative to integrate technological education into school science practice. Our starting point is a pre-service teacher course: "Technology and Science Education for Physics Lessons". Students are taught important differences between science and technology. Subsequently they have to create teaching sequences of practical activities including both perspectives. Thus they are given the chance to understand the importance of technology and how to integrate it adequately into science. We study the change of students' concepts of the differences between science and technology using mind mapping, written statements and questionnaires. Results show a change of students' perspective from naïve views of technology as applied science to a more process orientated understanding of technology.

Keywords: technology education; pre-service; science education; nature of technology

THEORETICAL BACKGROUND

In Europe science and technology are important for the wellbeing of the society. While the influence of technology on our daily life is strong there is a lack of interest to study subjects of this field. Programmes in the EU[1] and USA[2] are set up to increase the interest in science and technology education (Bybee, 2000; ITEA, 2000). Governments intend to increase the number of students and former academic workers. In Germany special MINT-Initiatives[3] are supported by the government. The aim is to raise the interest in these fields and thereby the number of students in these subjects. In the German educational system we have a counterproductive structural problem: While science is well established in schools technology is not. Technology is viewed as inferior to science.

Germany has a strong tradition in preparing workers in a dual system (working in a company and attending a vocational school). As many universities refused to set up engineering courses special universities for applied sciences (‘Fachhochschule’) were founded. There is no chance to gain general technology education at the Gymnasium (upper secondary school). Initiatives to establish technology as a general school subject failed in the 1970ies. Since then a lot of out-of-school learning environments were set up by companies and engineering associations, such as student labs, science museums and technology competitions. However, our starting-point is the regular school curriculum because we believe that technology cannot only be taught in out-of-school environments. We are aiming at a more systematic technology education and intend to develop pre-service physics teachers’ understanding for the necessity of technology education.

A pre-service teacher course: Science and Technology Education in Physics Lessons

Students in science education have no systematic technology education and tend to have naïve views about the nature of technology (Constantinou, Hadjilouca, & Papdouris, 2010). Students see technology as applied science and some even do not think that it is an academic discipline. Thus a pre-service teacher course is set up aiming at the change of concepts of the nature of technology. The idea is to explain the different perspectives and processes of technology and science (Eisenkraft, 2003; Wonacott, 2001; Euler, 2008.). Students have to plan a school project to use the new ideas in a specific situation. Possible topics are energy supply, production and automation, innovative engines, optimization of wings and Leonardo da Vinci’s machines. Students analyze curricula and have to make their own decisions about methods. They have to integrate learning aims and perspectives from both sides: science and technology. Consequently they have to rethink their attitudes and values referring to science and technology (Bell & Lederman, 2003).

RESEARCH QUESTIONS

What concepts do students hold about the differences and links between science and technology?

To which degree can students' concepts of technology be developed by special teacher training courses? To which degree can students' conceptual awareness of the differences and links between science and technology be developed?

DESIGN AND METHODS

We use a pre-post-test design to investigate the development of students' attitudes towards technology education and their understanding of the differences and links between science and technology (fig. 1). Students are asked to do a two-step-brainstorming: First they draw a mind map starting with 'science' and 'technology' already written on the sheet and are asked to complete the map using terms and links. Then they write a statement of about one page commenting the mind map. Finally they fill in a questionnaire about their former education in technology, a semantic differential about science and technology and their attitudes towards technology in school.

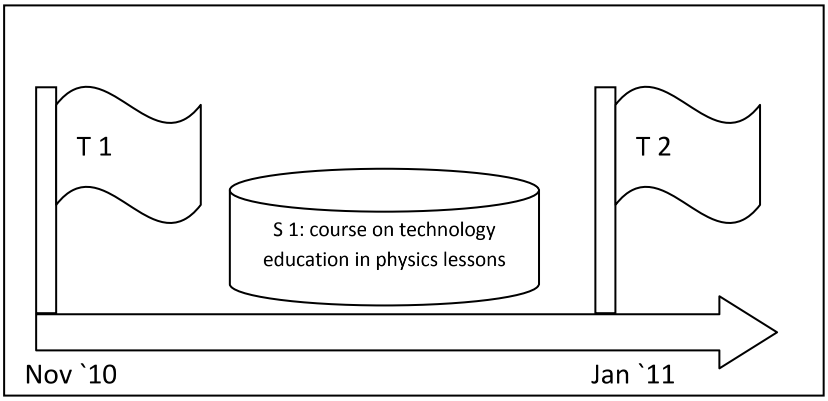

Fig 1: design of the study; intervention with pre/post-test

T1: mind map, statement, questionnaire
S 1: pre-service course for physics teacher students (theoretical input, comparative analysis of science and technology curricula, planning of a school project, presentation and discussion)
T 2: mind map, statement, questionnaire
49 persons filled in the questionnaire at T1 and 15 attendees of the seminar participated in the whole study T 1 – S 1 – T 2.

Due to the low number of students in the course statistical methods can rarely be used. To get more general information about former technology education and general attitudes we raised the number of students who filled in the questionnaire up to 50. The study will be continued with following courses in winter 2011/2012. We are now developing the questionnaire and planning to raise the number of participants (pupils, students, in-service teachers).

RESULTS

Questionnaire

The questionnaire was completed by 49 participants (physics teacher students, 60 % male). The attendees of the seminar also were physics teacher students who are in the master level (60 % male). Every participant had physics lessons at school (tab. 1). No attendee had technology lessons. Only one participant reported to has had technology lessons at school.

31 % of the schools had optional study groups for technology, 51 % a project group on stage equipment and event technology (tab 1). 22 % of the schools attended in technology competitions, 16 % offered other courses related to technology.

Tab 1: Optional technology courses at schools

	Optional study group technology	Project group on stage equipment and event technology	Participation in competitions	Other
Participants study	11 (32 %)	16 (47 %)	10 (29 %)	3 (9 %)
Attendees of the course	4 (26 %)	9 (60 %)	1 (7 %)	5 (33 %)
all	15 (31 %)	25 (51 %)	11 (22 %)	8 (16 %)

Students mainly perceive technology as applied science (fig. 2). In this aspect there are no differences between attendees and other students. Even the post test results show that this is a strong concept. This concepts is appropriate as one aspect of a sophisticated view of technology. But the analysis of the mind maps (chapter below) shows that the over emphasis on this singular aspect can be seen as a rather naïve view on technology.

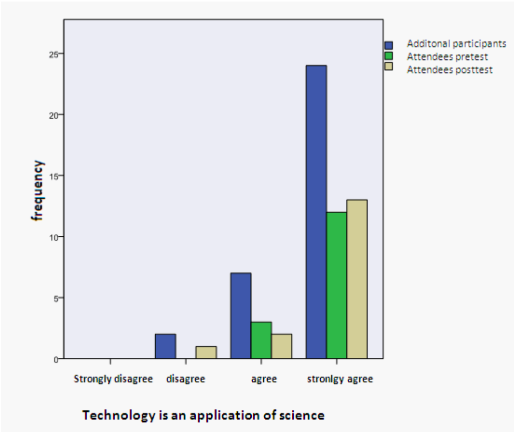

Fig 2: technology as an application of science

In the pre test students do not agree that technology is an independent academic discipline (fig. 3). Only in the post test students tend to agree that technology is an academic discipline even though their university has a strong emphasis on mechanical and electrical engineering. With larger test samples we expect to find significant differences. We interpret this as a learning outcome of the course where we focus on the processes of technology. Students get insights into the rich and valuable tools and procedures of academic technology. Through the seminar some of the students expressed their changing views of these aspects. Some even reported that they went through a conceptual change of their views of technology.

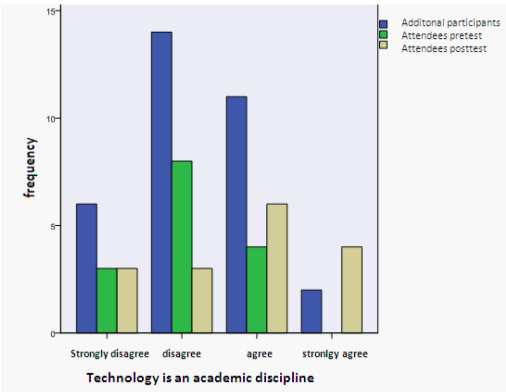

Fig 3: technology as an academic discipline

Mind Maps

Students link 54 % of all used terms to ‘technology’ in the pre-test. In the post-test 63 % of the terms are linked to technology (fig. 4). The terms linked to ‘science ‘slightly decline from 55 % to 52 % (pre to post test). From pre to post test the percentage of terms placed in the middle of ‘technology’ and ‘science’ raises from 12 % to 20 %.

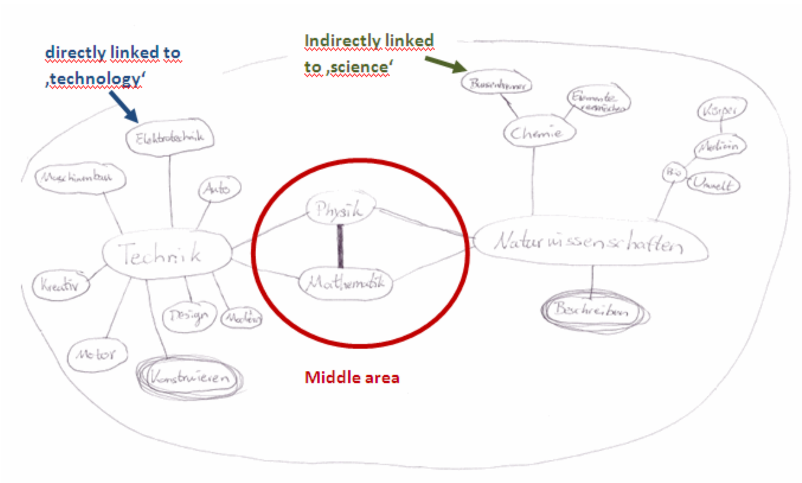

Fig 4: example map with comments

To indicate the interconnectedness of 'technology' and 'science' we counted the direct and indirect bridges from one to the other. Then we calculated the ratio of this number to the total amount of terms in each map. On average we find an increase of this indicator from 0,14 to 0,18. Due to the small number of cases we cannot rely on the result. Further studies with larger samples will show if the hypotheses driven from this study can be verified. In depth analyses of the bridging between 'technology' and 'science' have shown that there might be two classes of development from pre to post test. The indicator might not be appropriate to describe a general behavior. We find a group of students (I) who do rarely change their concepts and views of technology and science (tab. 2). On average they have the same or even a lower amount of links in their maps. Another group (II) of students shows a significant change of concepts and views. Interestingly the mind maps of those attendees show an increase of interconnectedness. We find 8 students in group I and 7 students in group II.

Tabelle 2: examples for the connection of technology and science

	pretest	posttest
I		II		
The attendees however developed on average a more appropriate understanding of technology. Additionally to the view of technology as an applied science one finds as well more developed opinions about technology as an independent academic discipline. Aspects like the final perspective, processes as optimization and design form their understanding of technology. Thus they consider technology more relevant for school education.

Interestingly some students use terms like fantasy, curiosity, and convenience to distinguish between science and technology. They contribute to a deeper understanding of scientific and technological processes which is often missing in teacher education and school science classes. In one map (5) we find terms like ‘progress’, ‘curiosity’, and ‘fantasy’. In another map (13) we find ‘danger‘, ‘responsibility‘, and ‘coincidence’. Further in depth analysis of cases will give an insight into the evoked associations. These examples demonstrate that the terms ‘technology’ and ‘science’ can be understood in many different contexts, e.g. education, society, ethics, academic system.

RESUMÉ

Findings approve that technology is mainly perceived as an application of science. The attendees of the seminar however develop a more differentiated perspective of technology and science. Especially they have deeper insights into interrelations between science and technology and the resulting effects on society. We are planning to conduct the course again, also for in-service teacher education. We assume that the understanding of the interrelations between science and technology is crucial for the development of technology education in schools. Results presented in this paper give reasonable prospect that a conceptual change in the views of technology and science can be triggered trough such a course. Thus we find it fruitful to develop different modules for in-service teacher training and to evaluate the impact of such an intervention.

HOW SCIENCE WORKS: A LONGITUDINAL STUDY OF PRE-SERVICE TEACHERS' FIELD EXPERIENCES OF SCIENCE CURRICULUM CHANGE IN ENGLAND

Rob Toplis[1] *and Charles Golabek*[2]

Email: c.golabek@uel.ac.uk

Abstract: This paper reports work by University providers with pre-service teachers into how a major revision of the curriculum in England, *How Science Works*, has been translated into practice in their schools. Data were collected by pre-service teachers over three years about their understanding, experiences, perceived challenges and resourcing of *How Science Works*. The results indicate that implementation of *How Science Works* continues to lie on a spectrum between two extremes referred to as creative implementation and restricted implementation; that pre-service teachers' have improved their understanding of the processes of science and how these relate to higher order thinking skills; that reliance on published resources remains high; that there is an increase in student-centred approaches and some shift from content towards process but that the dominance of assessment remains. Students' engagement with the new curriculum is variable, being most successful when teaching is appropriate to ability, actively involves students and is sufficiently challenging; engagement is negative where a content laden curriculum remains. The paper concludes that the key areas for change are higher order thinking skills, appropriate differentiation and a transition from teaching facts to developing concepts, with pre-service teachers being paramount as agents for change.

INTRODUCTION

This paper reports how a major change in the science curriculum, the inclusion of *How Science Works* in the National Curriculum for England, has been implemented in schools over a three-year period, as experienced by pre-service science teachers' reports. In doing so it seeks to add to knowledge about science curriculum change by providing insights into how a new curriculum initiative has been introduced in a range of secondary schools (ages 11 to 16 or 11 to 18 years) and identifies trends over the three-year period. This work can inform international science education researchers and curriculum developers about a model of curriculum change at a time when a number of countries are experiencing changes that reflect students' views about science, the relevance of science to their lives and their views about the advanced study of science (e.g. Jenkins and Nelson, 2005; Sjøberg and Schreiner, 2005). In doing so, this work will inform those involved with science teacher education at both initial (pre-service) and experienced (continuing professional development) levels to ensure that they are confident about the philosophy and practices for effective integration of change, in this case that of *How Science Works*, in science classrooms. In this paper we analyse both the variety of approaches to implementation and the trends over the three years of the project

BACKGROUND

In common with a number of countries worldwide (INCA, 2008), school students in England follow a statutory national curriculum for science that sets out programmes of study and level descriptions for the assessment of all 5 to 16 year olds (QCDA, 2007). Various revisions between 1989 and 2004 led to four main attainment targets that were essentially concerned with scientific enquiry (inquiry), biological, chemical, and physical processes. In 2004, a major change occurred that saw the inclusion of *How Science Works* where, at Key Stage 4 (14-16 years), teachers should ensure that the knowledge, skills and understanding of how science works are integrated into the teaching of science content (QCDA, 2007). Within the *How Science Works* programme of study are four main subsections: data, evidence, theories and explanations; practical and enquiry skills; communication skills; and applications and implications of science. These changes commenced in schools with Key Stage 4 in September 2006 and with Key Stage 3 (ages 11-14 years) in September 2008.

Changes to the 2004 curriculum originated at the instigation of prominent science educators that culminated in the document *Beyond 2000* (Millar and Osborne, 1998). This seminal document was the product of a desire to provide a vision of science education that addressed the needs and interests of young people as future citizens at the end of the 20th century. One important outcome from *Beyond 2000* was the inception of the Twenty-First Century Science project that was the first attempt to develop and pilot a major curriculum initiative and to use evaluations of the pilot to inform further development (Burden *et al*., 2007).

Whereas our previous ESERA paper (Golabek *et al*., 2010) reported how the new curriculum has been implemented, this paper reports the trends of these implementations over a three year period and takes into account the extension of the *How Science Works* strand into Key Stage 3.

Importantly, our interest as both researchers and teacher educators – and one related to *who* implements new approaches to teaching and learning – concerns the role of pre-service teachers (referred to as 'trainees') in implementing curriculum change. Taber *et al.* (2006, 64), in providing a rationale for including a project on ideas and evidence (part of the How Science Works strand) in the pre-service training year, highlights the concern that 'there may be limited good practice in many schools' and that pre-service teachers can become models of good practice. They are therefore more likely to be in the vanguard of change as change agents when they enter the teaching profession (Braund and Campbell, 2010). Trainees' developing awareness of curriculum change and schools' approaches to it have been raised in that they have had the opportunity to share these experiences with their peers, encouraging them to see this an important area in their future work.

RESEARCH QUESTIONS

In order to find out *How Science Works* for trainee teachers, we posed two research questions:

1. Is there a paradigm shift in terms of a change in the pattern of science education with a move from teaching facts to understanding concepts? This would represent a change in thinking, or *Mind set*.
2. Is there an associated change in pedagogy in terms of (i) *Mind set* (ii) *Methods* and (iii) *Materials*?

With trainees from a variety of science backgrounds, whether it be subject discipline, research, business or even their own experiences of school science, our first research question is important in order to gather data on their own understanding of *How Science Works* and their underpinning views about the way that science is taught. Our second question is rather more pragmatic in gathering data about how *How Science Works* is seen in practice. We want to know what changes have occurred in science classrooms in terms of the pedagogy involved and how this is supported. In particular we want to explore the changes in thinking about how science is taught and the effects of this on both teachers and students

METHODS

Three university providers of pre-service teacher education in and around the London region participated in this study with a cohort of 70 trainees during 2008 and 50 in 2009. The final year of the study, 2010, saw the participation of two University providers and a total of 44 trainees. Trainees study a one year course that includes University taught elements and two blocks of observation and teaching experience in schools. The study was carried out in two-stages. Stage 1 involved five questions that were emailed to trainees during their final period of school experience, to direct their focus on *How Science Works*. The questions were related to the three aspects of pedagogy in the research questions and provided a stimulus for trainees' thinking about *How Science Works*.

Q1: What do you understand by *How Science Works*? [Mind Set]
Q2: Describe the resources that are being used in your present practice school [Materials]
Q3: What are your experiences of teaching approaches to *How Science Works* at KS4? [Methods]
Q4: What challenges have you experienced with teaching *How Science Works*? [Methods]
Q5: How do you see that students receive *How Science Works*? [Mind Set]

Stage 2 involved small discussion groups in the final weeks of the University course. Trainees were then asked to summarise their discussions on a poster. They then went to the next questions and repeated the process adding to the responses recorded by the previous group. The data from the trainee groups of the providers were analysed collaboratively to categorise emergent themes.

A qualitative approach was adopted in order to provide open-ended responses that allow trainees to report both their understanding and observations for each question and in detail. Quantitative approaches using Likert-type responses would have provided us with data about what changes were experienced in schools, in response to closed questions, but would have been limited in the level of detail which was possible with the qualitative approach used. The use of emailed questions instead of interviews were used as a more efficient approach to surveying larger numbers of trainees over the limited time 'window' available and for providing a more convenient approach for data analysis. Furthermore, the use of agreed emailed questions between University providers was able to increase the level of reliability with the same questions asked to all participants

RESULTS AND DISCUSSION

Trainees' understanding of How Science Works

Trainees' own understandings appear to operate at two levels. At one level, that of their understanding content of the new curriculum, the relevance of science and its applications to real life, their perceptions remains similar over the three years of the study. At another level, there is an emerging trend with their increasing views about transferable, cross-curricular skills that related to higher order thinking skills (such as the nature of data and evidence, analysis and explanations) and an increased understanding of the processes of science and a better understanding of how scientists work. This is shown in this example:

> *It also makes them think about the concept of evidence and how science works in the way that theories only come about by evidence, and if something is contrary to it, then a new hypothesis must be made and tested.*

Despite comments of this nature, there remained a noticeable lack of any mention of history of science or scientists and the link to communication skills remained minimal.

In the mid 1950s, Bloom (1956) formalised the idea that different types of learning might require different levels of cognitive processing. He identified six levels: remembering facts, understanding their relevance and being able to apply this knowledge and understanding were classed as lower order thinking skills (LOTS). Important in their own right, but forming the base of a pyramid from which other higher skills are able to develop. The ability to analyse, evaluate and synthesise, and the ability to create new knowledge, are classed as higher order thinking skills (HOTS). These require a higher level of reasoning and intellectual processing such as critical thinking and problem solving and thus require a different approach to teaching and learning. These higher order skills are more difficult to master, but are considered more valuable as transferable skills particularly in application to new situations. It is the trend towards these higher order thinking skills that is more evident in the data over the three-year period of this study.

Resources used in practice schools

A heavy reliance continues over the period with the use of published resources, both text and ICT resources. Furthermore, there is an increased dependence on resources directly linked (and often published for) specific examination specifications. This further confirms the dominance of assessment, a 'teaching to the test' approach to science, particularly so at KS4. There are strong indications that teachers are pressed to complete the specified work within the set timescales. Practical work and developing manual skills, experimentation, data gathering and more open ended work, compared to previously prescribed practicals, takes longer to prepare and carry through a sequence of lessons. Preparing a class for discussion with time for research, planning, preparing presentations, all takes time. And yet at the end f it all there are still exams to pass! It is therefore hardly surprising that teachers in schools fall back on published and on-line resources.

Teaching approaches to How Science Works

We have noted a number of trends over the here years of the study. Debates and discussions remain an ongoing part of *How Science Works*. There is an increased use of short video clips and internet resources; increased adoption of student-centred approaches such as independent research and writing; a shift away from content towards process and with it a shift from the teacher as transmitter of content to facilitator, and the student as passive to active learner; a greater emphasis on investigative work. However, but there remain problems for the lower ability students (see below on challenges); there remains no change in teaching to the test with assessment taking a dominant position within science departments in schools. There are ongoing reports of a lack of time, resources, funding and teachers' understanding of *How Science Works* in the curriculum, including a lack of training with the new approaches and reports of a lack of departmental support.

On the positive side, enthusiasm and creativity in relation to *How Science Works* was depicted in the trainee responses that included broadening students' perspectives by a focus on the 'real life' of current affairs, contemporary and ethical issues, and giving students more responsibility by putting them in charge of their own decisions and judgements. Scientific ideas were reinforced by their applications. Teachers with a more positive mind set integrated *How Science Works* into their schemes of work, which led to teaching methods linked to the world around them, engagement with current affairs through newspapers and the Internet and adaptation of materials to address learning styles. Teaching specific terminology was an anticipated need, and methods such as drama were used effectively. However, these positive changes over the three-year period to curriculum change tended to be in the minority.

On the more negative side, trainees detected that some teachers were still stuck within a content laden curriculum mindset, not having yet prepared for the needs of students and anxious about workload issues to cater for the new curriculum. They had anticipated neither the difficulties that lower ability students would have in analysis and evaluation of evidence nor the National Curriculum requirement to improve communication skills. A perception that content needed to be delivered more slowly meant that a tension was evident as teachers struggled for time. Students failed to see the purpose of what they were being taught because the teaching was insufficiently related to students' interests.

Challenges with teaching How Science Works

Implementation of *How Science Works* in schools lies on a spectrum between two extremes which we refer to as *creative implementation* and *restricted implementation*. With creative implementation, trainees report that there have been some creative transformative practices to meet the aims of the recent National Curriculum. There is a trend in students being encouraged to take responsibility particularly in planning practical work and in discussions. This approach has resulted from forward planning, which has involved all staff in the adaptation of existing resources and the development of bespoke materials. *How Science Works* was fully integrated into the core of schemes of work together with appropriate training for both teachers and technicians.

With restricted implementation, teachers seem unsure of the new curriculum and what *How Science Works* is about. Trainees seem to be picking up negative signals from some schools that *How Science Works* is not being integrated into schemes of work. However, commercially produced schemes of work and CDs are adopted. Some teachers have difficulty in making the transition from teaching facts to developing concepts so that the broader aspects of *How Science Works* are bolted on to the existing curriculum. There seems to have been a lack of forward planning and teaching is centred on assessment with tasks and examination questions being used from the end of Key Stage 3.

How students receive How Science Works
On the positive side, the trainees report that students enjoy *How Science Works*. They are keen and interested, particularly so where the subject matter is relevant to their experience and with engaging practical work. Lessons are more enjoyable and productive as relating things to everyday life makes science fun. *How Science Works* activities are useful and achievable, with the majority of trainees believing that hands-on practicals to be the most enjoyable. For low achievers, less theory with more examples and activities appears to be the way to keep students engaged. The more able students respond well to investigative skills development like evidence based thinking, data collection, the scientific method and critical analysis. *How Science Works* has to be specifically tailored to meet the needs and differing ability students. On the negative side, there is continuing difficulty with the need to engage students at different levels; where appropriately challenging work for the more able produces problems such as disengagement and difficulty for the less able. Conversely, work that is designed to engage the less able can lead to boredom and disengagement with the more able. Students continue to have difficulties with vocabulary, definitions, understanding key concepts, such as variables, validity and reliability. There is some evidence that Key Stage 4 students lose interest in *How Science Works* because of the overarching pressure of external examinations. Students are not really aware that *How Science Works* now forms the core of science learning and instinctively look to be taught in a more traditional manner. This is not helped by some of the more restrictive departments where there appears to be difficulty with understanding the concept and integration of *How Science Works* and with implementing it, including little deviation from a previous teaching style, which may be a response to the legacy of past curriculum over-prescription.

Over the three-year period of the study we have observed an increased awareness of the need for differentiation. There are indications that both low and high ability students can engage in and enjoy this new approach but at differing points on the teaching and learning spectrum. For lower ability students, the materials, level of engagement, pace of lessons must be tailored to their needs. In this environment the more able quickly become bored and disengaged. For the higher ability students, operating at the analysis-evaluation and even creative levels is a stimulating challenge to which many respond with enthusiasm. For the less able, this is beyond their immediate capabilities and results in confusion, frustration and very quick disillusion with learning, which then often leads to behavioural and classroom management issues.

CONCLUSIONS AND IMPLICATIONS

The findings of this longitudinal study indicate a shift in adoption of new pedagogies and approaches associated with curriculum change, that of *How Science Works*, in science classrooms. This shift is demonstrated with a move from a restrictive to a more creative implementation of *How Science Works* over the three-year study, to a realisation by trainees of the importance of differentiation to provide challenge and engagement for all students, and to the increasing importance of higher order thinking skills and their transferability. Trainees' own understanding of How Science Works has improved in terms of the nature of transferable, cross-curricular and higher order thinking skills, and an increased understanding of the processes of science with a better understanding of how scientists work. However, trainees report that assessment still remains a dominant feature in many schools, as does an increasing reliance on published resources.

Trainees' time spent in schools, time that takes up two thirds of the one year pre-service teacher education course, is an important part of their education programme as they develop as beginning teachers. This is especially important at a time of dramatic curriculum change in schools that goes beyond trainees seeing classrooms in terms of personal theories, generalisations about students or ways of representing subject knowledge (Furlong and Maynard, 1995), but with an enhanced awareness of the pedagogies of science education and the changes that affect teachers' work. The timing of eliciting trainees' responses were intentionally directed towards the end of the one-year teacher education course as being a time when they would be expected to have moved beyond the earlier stages of idealism, personal survival and dealing with the difficulties associated with this, to reaching a plateau (Furlong and Maynard, 1995) and being at the final stages of moving on to understanding the constraints involved with teaching and learning, beyond the 'good ideas' for teaching science and into the growth of professional knowledge. We are therefore starting to deal with trainees at the autonomous stage of their teacher education journey, a stage exemplified as a broadening of their repertoire of strategies, a deeper understanding of the complexities of teaching and learning and a consideration of the social and moral dimensions of their work.

Curriculum change and resulting pedagogies are important aspects of a beginning teacher's continuing development as responsive, thoughtful and skilled practitioners. The trainees' reports of practice in this study have allowed their awareness of curriculum change and schools' approaches to it has been raised, and they have had the opportunity to share these experiences with their peers, encouraging them to see this as an important area in their future practice. It is through these reported experiences that beginning teachers can become vanguards for exemplary practice that involves them as agents for change when they enter the teaching profession (Braund and Campbell, 2010).

PRACTICAL STUDY ON ARGUMENT SKILL IMPROVEMENT IN PRE-SERVICE TEACHERS

[3]Graduate School of Education, University of Miyazaki
[4]The Japan Association of National Universities

Abstract: Recently science education has focused on the development of learners' argument skills. Argument skills are believed to be an important quality not only in learners but also in teachers. Yet it is pointed out that teachers' argument skills are limited (Zohar, 2008). In this study, we implemented a curriculum aimed at improving pre-service teachers' argument skills and effectiveness.

Developed by Seethaler & Linn (2004), the curriculum addresses genetically modified foods as a socio-scientific issue. Our target group comprised 43 Japanese pre-service teachers. Before and after implementation of the curriculum, surveys were conducted concerning the issue of "nuclear power generation," a topic different from what our pre-service teachers had learned through the curriculum. Based on the Knowledge Integration scoring scheme developed by Seethaler & Linn (2004), of the elements studied, "evidence against chosen position" and "conclusion to overall argument" showed a particularly significant improvement in scores from before to after curriculum implementation. Significant correlations between these two elements after curriculum learning were also identified.

These results indicate that the curriculum is effective in argument skill improvement, not only in junior high school students, but in pre-service teachers as well. Also, it became clear that this curriculum improves 1) the skill element of using not only evidence that supports one's argument, but also evidence that contradicts one's argument and 2) the skill element of drawing weighted conclusions. It is suggested that promoting the use of evidence produced by conflicting standpoints can be a design principle for curricula aimed at improving argument skills.

Keywords: argument skill, pre-service teachers, evidence, socio-scientific issue, design principle

BACKGROUND

Argument is a series of verbal forms intended to establish a certain claim through, for instance, backing and rebuttal, or a series of verbal exchanges that contain such elements (Toulmin, 1958). In recent years, science education places importance upon and pays attention to the improvement of argument skills in learners (Erduran & Jiménez-Aleixandre, 2008). PISA's interpretation of scientific literacy includes the capacity to draw evidence-based conclusions with respect to scientific questions (OECD, 2007). Argument skills constitute an important quality not only for learners, but also for teachers engaged in giving lessons to learners.

THEORETICAL FRAMEWORK

In today's society, where issues concerning science, technology and the environment abound, learners are required to have argument skills to establish evidence-based claims, considering conflicting standpoints (Duschl & Osborne, 2002). Against this background, present-day teachers must have not only content knowledge or pedagogical content knowledge, but also high-order thinking skills, such as argument skills (Zohar, 2008).

In reality, however, it is noted that teachers' argument skills are limited. For example, on the basis of her studies targeted at pre-service teachers, Zohar (2008) points out pre-service teachers' inability to connect evidence to claims, and their propensity toward hasty conclusion and generalization.

Unless teachers have high argument skills, it is extremely difficult to improve argument skills in learners. For this reason, we thought it an urgent task to obtain knowledge concerning the improvement of teachers' argument skills, if we wish to improve said skills in learners.

PURPOSE OF THE STUDY

Targeted at pre-service teachers, this study implemented a curriculum designed to improve argument skills, and evaluated its effectiveness. The curriculum, which addresses genetically modified foods as a socio-scientific issue, was put together by Seethaler & Linn (2004). While the Seethaler & Linn curriculum (2004) is geared to junior high school students, it is also predicted to be effective for pre-service teachers not particularly trained in argument concerning socio-scientific issues.

In this study, we asked the following two research questions:

a) Does the curriculum of Seethaler & Linn (2004) improve pre-service teachers' argument skills?

b) If the answer to (a) is positive, which elements of the argument skills does the curriculum improve?

RESERCH DESIGN AND METHODOLOGY

Subjects

Subjects of this study comprised 43 third-year students at the education departments of Japanese national universities who were seeking teacher's qualification. None had experienced learning about argument concerning socio-scientific issues.

Duration of study

A total of 6 class hours (90 minutes ! 6 times) in October-November 2010

Curriculum outline

This study used a curriculum developed by Seethaler & Linn (2004). Table1 shows the process of our curriculum. At the outset, we raised the issue of genetically modified food development and had the students read materials to obtain basic knowledge of gene recombination technology and its differences from natural crossbreeding. We then presented materials, each either for or against this issue, and conducted an activity involving argumentative discourse using those data (Figure1). At the end of the curriculum, students were required to write a position paper expressing their respective standpoint .

Table1. The process of our curriculum

process	class hour	activity
1	1	Discuss about the issue of genetically modified food development.
	2	Read materials to obtain basic knowledge of gene recombination technology and its differences from natural crossbreeding.
2	3-4	Read materials each either for or against this issue as evidences.
3	5	Callenge an activity involving argumentative discourse using evidences.
4	6	Write a position paper expressing their respective standpoint.

Figure1. An activity involving argumentative discourse using data (process3)

Test and survey

To assess pre-service teachers' argument skills, tests were conducted before and after curriculum implementation regarding to the issue of "nuclear power generation," different from the issue learned through the curriculum. In these tests, each student was required to read materials expressing opinions both for and against nuclear power generation (Table2), and to write a position paper (one A4 page) supporting his or her position concerning this specific issue. In other words, argument used for the tests were identical in structure to those concerning the genetically modified foods issue addressed in the curriculum, but differed in terms of content of argument. Using the questionnaire method, the time spent on each survey was 20 minutes.

Table2. Opinions both for and against nuclear power generation

For nuclear power generation	Against nuclear power generation
Nuclear power generation are safe.	Nuclear power generation are not safe.
Nuclear power generation are good for environment.	Nuclear power generation are bad for environment.
Nuclear power generation make vast electrical energy.	Nuclear power generation cost oceans of money.

Analysis

Based on the Knowledge Integration scoring scheme developed by Seethaler & Linn (2004), we scored responses concerning the survey subject. This scheme was developed in accordance with Toulmin's framework concerning the structure of argument (Toulmin, 1958). Of the five elements constituting the knowledge integration scoring scheme, for "evidence in favor of chosen position," "evidence against chosen position," and "counter-evidence to evidence against their position," a response without description was scored "0," a response with descriptions "1," and a response with ample explanation "2." For "normativity," a response that was not appropriate was scored "0" and one that was appropriate "1." For "conclusion to overall argument," a response without a conclusion was scored "0," a response containing either a pro or con conclusion "1," a response that weighs evidence from both standpoints but contains inappropriate pieces of evidence "2," and a response weighing evidence from both standpoints with all pieces of evidence contained therein appropriate "3." The highest score, therefore, is 10. Two of the authors conducted the scoring independently from each other. The concordance rate turned out to be 89.2%. Discordance was corrected through consultation.

DATA ANALYSIS AND RESEARCH FINDINGS

Table 3 shows total scores and score distribution for each element before and after the curriculum learning. As a result of Wilcoxon's signed-rank test, total scores improved significantly from before the learning to after the learning (Z=2.33, $p < .05$). Of the scores given to each element, those for "evidence against chosen position" and "conclusion to overall argument" showed a significant improvement from before the learning to after the learning (Z=1.81, $p < .10$; Z=2.32, $p < .05$). Assessment using Spearman's rank correlation coefficient revealed significant correlation between these elements after the learning ($r = .33$, $p < .05$). Meanwhile, no significant change was identified from before to after the learning with respect to "evidence in favor of chosen position," "normativity" and "counter-evidence to evidence against their position ($p > .10$).

Table3. Distribution of knowledge integration scores.

Element of argument	scores	Number of students achieving each KI score	
		pretest	posttest
Evidence in favor of chosen position	0	2	I
	1	28	32
	2	13	10
Evidence against chosen position	0	9	1
	I	30	39
	2	4	3
Normativity(presence/ absence of non-normative ideas)	0	1	3
	1	42	40
Counter-evidence to evidence against their position	0	32	27
	I	II	14
	2	0	2
Conclusions to overall argument	0	4	1
	I	35	29
	2	0	0
	3	4	13

CONCLUSIONS AND IMPLICATIONS

The above results are believed to indicate that the curriculum developed by Seethaler & Linn (2004) is effective in argument skill improvement, not only in junior high school students, but also in pre-service teachers. Furthermore, it became clear that this curriculum improves 1) the skill element of using not only evidence that supports one's argument, but also evidence that contradicts one's argument, and 2) the skill element of drawing a weighted conclusion.

Jiménez-Aleixandre, M. P. (2008) proposes, as design principles of argumentation, "choosing among two or more competing explanations or theories" and "backing their claims or choices with evidence." The curriculum developed by Seethaler & Linn (2004) is characteristic in promoting the use of evidence from conflicting standpoints. From these earlier observations and the results of this study, promoting the weighting of conclusions using evidence against one's argument can be a design principle of a curriculum that helps improve argument skills concerning socio-scientific issues, regarding which several different arguments can be made.

Meanwhile, this study indicates that students able to reach weighted conclusions after the curriculum learning represented only about 30% of the survey group. The study also revealed that no improvement was achieved for the element of rebuttal using evidence. In the years ahead, therefore, studies must be conducted with regard to learning support tools that help improve these elements.

NANOSCIENCE AND NANOTECHNOLOGIES EDUCATION : TEACHERS' KNOWLEDGE

Virginie Albe[1]
[1]STEF, Ecole Normale Supérieure de Cachan

Abstract: "Nano Education" is an emergent field of research, in line with research in nanosciences and nanoteachnologies. Curriculum design to integrate nano in education, from kindergarten to university is also an intense field of interests. Recent efforts have been devoted to document students understanding on nanoscale, to develop and implement innovative "nano" devices for teachning and to train science teachers on nano. Inn this paper, science teachers understanding of nano and intentions to teach nanos were investigated in the context of a summer school. Pre and post questionnaires were used. ategories were elaborated by an iterative coding process. Pre-post tests comparison of teachers' knowledge show that nanoscience and nanotechnologies mostly defined a minima by the nanoscale size in the pre-test were also apprehended with specific physical properties and applications in the post-test. Teachers tend to favor specific designed teaching activities to integrate nanoscience and nanotechnologies in class. Results also suggest an openness to curriculum activities in relation to educative aims broader than science concepts learning. Teachers intentions show extra-discipline based curriculum activities with educative aims in relation to an understanding of science in the making, argumentation, information literacy and citizenship education. This encourages to develop science education research linked to the design of teaching activities on a nano-literacy.

Keywords: Nanosciences - Nanotechnologies - Secondary education - Curriculum development - Nanoliteracy

BACKGROUND, FRAMEWORK AND PURPOSE

Nanoscience and nanotechnology are often presented as a new scientific revolution or a new frontier to overcome that would generate tremendous economical gains (Roco, 2003). They also raise debates in society related to health and environmental issues, ethical concerns associated to modification of human beings and transhumanism, social and political issues linked to individuals data security and discussions about science and technology developments in democratic regimes (Berube 2006; David & Thomson, 2008; Lemley, 2005; Shapira, Youtie, Porter, 2010; Sheetz, Vidal, Pearson & Lozano, 2005). In such a context of controversial science and technology developments, education is presented as the major mode of science-society relationships regulation. Recent review of literature on nanoscience education has showed four emergent domains of interest for curriculum development and science education research (Hingant & Albe, 2010) : curriculum contents, approaches and purposes for nanoscience education at all levels of schooling, students' representations of size and scale and particularly nanoscale, specific instrumentations for nanoscience and nanotechnology teaching, science teachers training in nanoscience and nanotechnology. In this latter emergent research topic, this paper aims to contribute to our understanding of science teachers knowledge and representations about nanoscience and nanotechnology and their integration in science teaching.

RATIONALE

Literature on teachers professional development on nanoscience and nanotechnology has focused on the design and evaluation of training programs aimed to favour nanoscale science and engineering integration into teaching (Blonder, 2011; Daly, Hutchinson & Bryan, 2007; Hutchinson, Bryan & Bodner, 2009; Tomasik et al., 2009). Pre-post tests comparisons showed that teachers' knowledge improved a lot (Blonder, 2011; Tomasik et al., 2009) and two teaching strategies have been identified from teaching sequences produced by the teachers during training program : one consisted of integrating nano-related topics into the whole science curriculum and the other to add a specific nanoscience module into the curriculum (Tomasik et al., 2009). Teachers expressed more willingness to introduce an extension of the curriculum on nanoscience and nanotechnology rather than teaching a lesson on a completely new specific nano content (Daly, Hutchinson & Bryan, 2007). The introduction of nanoscale science into the curriculum is envisaged by teachers on a discipline base and interdisciplinary activities then seemed difficult to apprehend (Daly, Hutchinson & Bryan, 2007). Factors have also been identified for teachers' reasons to implement nanoscience lessons in class : relevance, student motivation, curriculum inflexibility, technical aspects and content knowledge (Hutchinson, Bryan & Bodner, 2009). Interviews with teachers showed that teachers were not at ease with students' questions in class and felt their scientific knowledge was not sufficient.

Teachers conceptions of nanoscale sizes have also been assessed by questionnaires and card sort tasks (Jones et al. 2008). Results showed that experienced and novice teachers' knowledge about small scale were poorly mastered. Experienced teachers better performed at nano-scale measurements than novice teachers. As we ever mentioned when reviewing literature, teachers nano related content knowledge needs research efforts (Hingant & Albe, 2010). In this context, the purpose of this paper is to document teachers' knowledge and intentions to teach nanoscience and nanotechnology. An empirical study was carried on before and after a one-week summer school on nanoscience and nanotechnology for French secondary science teachers.

METHODS

The 2010 E2phy summer school was the tenth issue of a series of yearly events dedicated to science teachers from secondary and higher education. It emanates from a group of teachers and researchers from research institutions[1], scientists and teachers unions[2] with the aim to promote scientific research, inform teachers of recent science developments and favor links between schools and research centers.

The 2010 summer school was focused on physics of the nanoworld. It included lectures on advanced domains in nanosciences, social impacts of nanosciences (ethic, health, toxicity, law, regulation-jurisdiction...) given by French researchers well-known in their respective fields, lab-work, visits of research centers and special events opened to a large public devoted to discussions on research in nanoscience and their societal impacts.

The science teachers attending the summer school knowledge on nanoscience and nanotechnologies and intentions to teach nanoscience and nanotechnology have been collected with pre and post questionnaires.

Questionnaires were structured into two parts : first on nanoscience and nanotechnologies and second on nano-education. First part consisted of five open questions (identical for pre and post tests) : According to you, what are nanoscience and nanotechnologies? What are the characteristics or specificities of nanoscience and nanotechnologies ? What do you think of the stakes, interests, strategies of research in nanoscience and nanotechnologies ?

Nanoscience and nanotechnologies developments raise debates, particularly on health and environment effects, did you hear about that ? According to you, what is debated ? What definitions of nanoscience and nanotechnologies do you give or would give in class ? Second part of the questionnaires consisted of four questions (identical for pre and post tests : What do you teach in nanosciences ? What curriculum contents do you think could be linked to nanosciences ? With what forms ? What finalities ?) and three additional open questions for the post-test to assess the summer school: what did you gain from the summer school ? What do you think you can integrate into your teaching ? On the opposite, what do you consider as poorly adequate for your teaching ?

125 questionnaires have been collected for the pre-test and 47 for the post-test. All answers were transcribed and coded with categories that emerged through 3 rounds of analysis. As a first step, two coders elaborated categories of answers independently, then confronted their categorisations to build consensus categories (second step). As a third step, the previously elaborated categories were revised through another round of coding. For statistical analysis, Sphinx software was used.

RESULTS

Science teachers' knowledge and representations on nanosciences and nanotechnologies

A large majority of teachers, both in pre and post-tests, consider that nanoscience and nanotechnologies are knowledge relative to the nanoscale, and for some teachers it is a new domain with specific applications. Characteristics or specificities of nanoscience and nanotechnologies from the teachers viewpoints also mostly concern the nanoscale then technological developments, and a link with quantum mechanics is underlined in the pre-test.

In the post-test, teachers also focused on new properties specific to this scale, raising technological difficulties and debates. Stakes and interests are focused in teachers responses to the pre-test on medicine, electronics and information technologies within the context of international competitiveness and on economical and social registers in the post-test.

Teachers were mostly aware of debates raised by nanoscience and nanotechnologies both in pre and post-tests. Teachers underlined mostly health, nano-particles toxicity and interactions with living organisms, and environment in a lesser extent in both pre and post-tests. Moreover in the post-test, they added legal, political, social and economical issues related to nanosciences and nanotechnologies. They underlined the absence of epidemiological results in the pre-test and mostly health and interactions with living organisms, and environment in a lesser extent in the post-test.

Science teachers' viewpoints on nano curriculum integration

Definitions of nanoscience and nanotechnologies to give in class are mostly focused on the nanoscale size and linked to knowledge on atoms and molecules for both pre and post-tests, and on the idea of a new domain with specific applications and physical properties in the pre-test (more rarely in the post-test for the latter). No answers of lack of knowledge were present in the post-test.

A majority of the teachers declared that at that time they don't teach nanoscience and cited curriculum contents that could be linked to nanosciences :

size and scale,
chemistry notions,

optics and medicine applications for the most cited (both in pre and post-tests) and electronics and size and scale in the post-test.

High-school teachers were the ones who contributed the most to the answers on that question about curriculum contents.

Forms of teaching envisaged are specific educative activities dedicated to the exploration and documentation of a new scientific domain in both pre and post-tests. Specific lessons in the science class are also mentioned in the pre-test according to the finalities of showing science in the making, developing engagement in science and understanding of scientific concepts.

In the post-test, collaboration with research labs, debates and video presentations are cited within finalities of showing science in the making, developing engagement in school science, understanding of scientific concepts, contributing to information literacy, citizenship education and learning to debate.

Teachers' evaluation of the summer school

In responses to the three additional open questions for the post-test, teachers expressed that from the summer school they gained knowledge on nanoscience and nanotechnologies and on nanoscience and nanotechnologies research, ideas for pedagogical activities and personal reflections. They considered that they can integrate informations and knowledge on nanoscience into their teaching.

CONCLUSIONS AND IMPLICATIONS

Pre-post tests comparison of teachers' knowledge show that nanoscience and nanotechnologies mostly defined a minima by the nanoscale size in the pre-test were also apprehended with specific physical properties and applications in the post-test. This result on teachers knowledge improvement through training programs converges with literature (Blonder, 2011; Tomasik et al., 2009). Teachers tend to favor specific designed teaching activities to integrate nanoscience and nanotechnologies in class. This result may converge with the previously identified teaching strategy of teachers privileging an extension of the science curriculum on nanoscience and nanotechnology (Daly, Hutchinson & Bryan, 2007) with reasons based on relevance, students motivation and content knowledge (Hutchinson, Bryan & Bodner, 2009). It also differs from literature stating a discipline base in teachers intentions (Daly, Hutchinson & Bryan, 2007) and on the opposite suggests an openness to curriculum activities in relation to educative aims broader than science concepts learning. This encourages to develop science education research linked to the design of teaching activities on a nano-literacy.

SCIENCE TEACHERS, POLICIES AND EDUCATION RESEARCH. ANALYSIS OF SURVEYS CONDUCTED IN SIX COUNTRIES

Emilio Balzano[1], Francesco Cuomo[1], Ciro Minichini[1], Marco Serpico[1]
[1]University of Napoli “Federico II”, Italy

Abstract: It is broadly agreed that the relationship between teachers’ beliefs and science education research results is complex and requires additional investigations and new approaches to understand the role of specific resources and constraints. Deeper investigation is needed concerning the distance among teachers’ feelings and expectations, the kind of educational research they know and the models of self-training that can be proposed in order to improve teacher knowledge and practice, supporting and focusing instruction in productive directions. The present research has been conducted, in the framework of the EU-funded TRACES project, in six countries (Argentina, Brazil, Colombia, Israel, Italy and Spain). Among all partner countries 1900 questionnaires were collected and 164 people (teachers, principals, researchers and policy makers) participated in interviews and focus groups. Findings from the comparison of the national surveys show the existence of tensions among all components of the education system. In the paper we analyze those concerning the relationships (and distances) of the school teaching from the national governance (guidelines, programs, assessment), on the one side, and educational research on the other side. Discussing the results we want to make a contribution to identify strategies and methods of investigation to figure out how to get answers to open questions of research that have not yet been sufficiently investigated.

Keywords: research-to-practice gap, evidence-based teaching, teachers’ beliefs, school system, education policies

BACKGROUND AND PURPOSE

An accumulating body of literature suggests that the gap between research itself and practice in science education is wide and rooted in a complex system of factors. In particular, we know that although teachers regard research evidence as valuable for they work, they are reluctant to adopt change if evidence does not resonate with their conceptions, beliefs and professional experience. The contribution we propose is the result of an international survey focused on the relationship between research and practice in science education undertaken in the framework of the TRACES project (see www.traces-project.eu), in which Italy, Spain, Israel, Brazil, Argentina, Colombia are involved. We use the findings from our surveys to identify key factors in the research-practice gap and suggest open issues and the way to address it in further research on the subject.

RATIONALE

Although it is well known that a deep gap separates educational research findings and real world school practice, research base about the links between aspects such as students performance and teachers’ preparation, beliefs and teaching approaches, resources available, interaction with principals, colleagues and pupils’ families, role of policies and curricula is still disparate and uneven (NRC, 2010; Lederman, 1999; Mellado, 1998). We know that research is crucial for improving science education (Duit, 2006). On the other side, fostering evidence-based change in teaching practice implies resonating with teachers' professional experience and beliefs about science education (Ratcliffe, 2005). Research findings are not likely to have an impact if they are not perceived as consistent with real-world practice conditions, such as availability of resources, average number of students per class, curricular constraints, teachers' pre- and in-service training. Bridging the research-practice gap in science education and sustaining the ongoing improvement in teaching and learning requires therefore more extensive investigation into all such aspects of the teaching reality. Recommendations and research agendas about a number of open questions for what regards improving evidence-based science teaching have been proposed in the literature (Osborne, 2008; NRC, 2010; NRC 2007). Further research is need on issues such as the relationship between different systemic factors in science education; how practice is influenced by policies, research and societal factors; how much policies are informed by research; how research-informed teaching improves students' performance; what is the role of teachers' beliefs and of their conceptions of science and pedagogy; what is the role of the context; what are the conditions that sustain or hamper effective teaching (see e.g. NRC 2011 and references therein).

METHODOLOGY

Our data include answers to a questionnaire administered to thousands of teachers in the six countries involved in TRACES and interviews and focus groups conducted with a smaller scale sample population of teachers, principals, policy makers, teacher educators and researchers in science education. The questionnaire includes both closed and open questions. A common form of the questionnaire was agreed at the consortium level. The common questionnaire was then localised – not simply translated – for application in each partner country. We considered that mere translation, rather than guaranteeing better comparability, would have provided less reliable data. In each partner country, some of the questions were adapted to the local context in order for the target group to understand their meaning as it was originally intended at the consortium level. The complete common questionnaire (in English) can be found in appendix to the report D3.1 on the TRACES website. The localised versions of the questionnaire can be found in the D2.1-6 reports. Our large-scale data include 1900 completed questionnaires, while on the small scale 164 people were involved. The detailed record per country is shown in Table 1.

	Argentine	Brazil	Colombia	Israel	Italy	Spain	Tot
Questionnaires	479	145	215	64	790	207	1900
Interviews / FG's	11	29	30	34	45	15	164

Table 1. Small- and large-scale survey samples in each partner country

Questionnaires have been assumed as the primary source of information, while interviews and focus groups represent a follow-up study, allowing for a deeper interpretation of the results emerging from the questionnaires. The comparison of the national surveys data started from identifying analogies and differences in answers to the teachers' questionnaire. The chart in Fig. 1 represents the overall answers to one of the core questions in the questionnaire (Q8: "In order to improve teaching and learning of science at school, do you think the following actions are?"), with agreement-disagreement with each item in the multiple choice measured on a 4-grade Likert scale.

As the chart shows, the majority of the teachers perceives all items in the multiple choice as at least relevant in order to improve science teaching, so expressing a strong need for structural changes in their extent practice. Nevertheless, a ranking in the importance attributed to the different actions is also quite evident. This ranking was quantitatively tested according to the non-parametric Mann-Whitney U-test. The main emerging issues can be summarized as follows:

a. Little relevance attributed to changes in curricula and official guidelines (item 1);
b. Little relevance attributed to changes in the assessment criteria (item 3);
c. Strong need for circulation of ideas and resources, but not for the involvement of external actors (items 2,8,9,10);
d. Strong need for material resources and in particular for lab facilities (items 11,12).

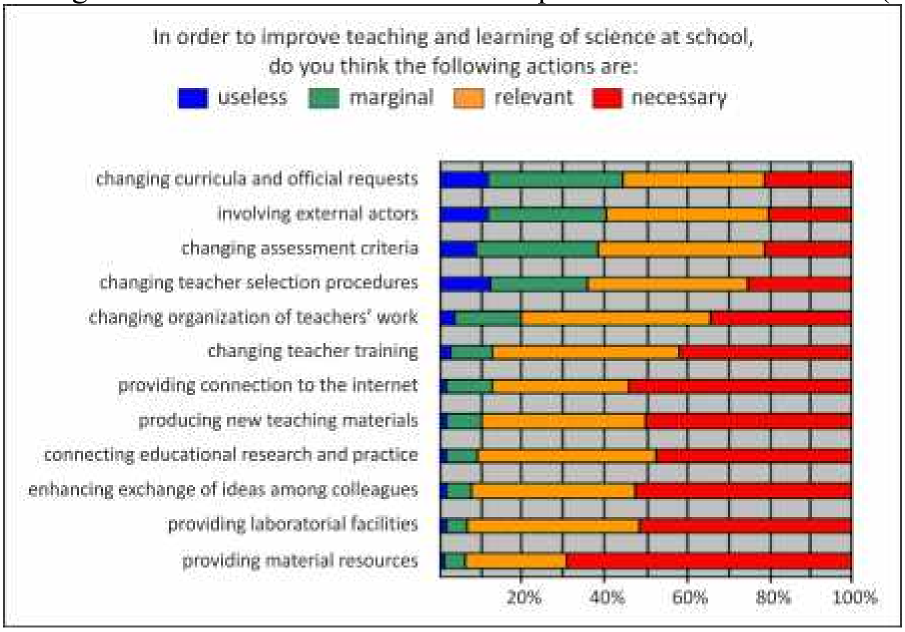

Fig. 1 Overall answers to Question 8 (large-scale sample)

These issues have been considered as emerging indicators of the tensions between teaching practices and policies (a., b.) on the one side and teaching practice and science education research (c., d.) on the other. Comparison of the qualitative data from interviews and focus groups allowed for a deeper insight into stakeholders' perspectives about elements a.-d. and an interpretation of the reasons of their emergence. In order to analyse these data, a qualitative content analysis approach based on text coding has been used.

RESULTS

In this paper, we discuss issues a.-d. listed in the previous section on the basis of findings from the main categories (occurrence above 10%) emerging from our text-coding analysis of qualitative data.

Tensions between educational policies and teaching practice

Teachers expressed low interest in "changes to the official requests" as a means for improving science teaching (a.). With slight differences in percentages from country to another, this item was one of the less valued in all our surveys. The emerging picture is confirmed when one cross compares these answers with those to Q1 (sources of the important ideas for science teaching) and Q9 (sources of ideas to improve teaching practice), in which the item "official documents" is very poorly represented (by far the less mentioned item with frequency lower than 10%).

In teachers' perspectives, the little relevance attributed to changing official requests is correlated to a number of factors. Teachers perceive a deep separation between the contents and goals of official documents and the real-world working conditions. Mostly, this is expressed with regard to lack of adequate time and material resources in order to fulfil the requests, or in terms of incapability of meeting students' needs related to a specific socio-cultural context. This remark is often connected to the lack of involvement in the design or evaluation of policies, referred to as one of the elements contributing to create the gap with the actual teaching practice.

Moreover, even if some teachers do value the rationale of official indications they often mention an absence of correspondent adequate training programmes. All the national surveys highlight teachers' general need for more specific training in order to be able to manage the contents of science curricula. Lack of specific training programmes developed to support the latest science education reforms is also referred to in almost all the involved countries. The perceived inadequacy of preparation often leads to a difficulty in complying to the official requests because they are poorly understood and hardly translated into practice.

The large majority of teachers seems to give prominence to practice as the main source of training (in the questionnaire, 77% of the sample indicates *professional experience* as the main source of inspiration for their teaching) and this habit is often translated into inertia in moving from a well-established practice based on experience and know-how.

Besides personal experience, a large majority of the sample in all countries referred to the enhancement of the exchange of ideas among colleagues as a strongly relevant change for the improvement of science teaching (Q8). This is also confirmed by answers to questions Q1 and Q9, in which colleagues are always referred to as one of the most valuable sources of ideas for science teaching.

At the same time, from interviews and focus groups emerges that the actual communication among teachers is often (perceived as) limited to issues related to the solution of organizational problems and institutional opportunities for dialogue usually do not foster a more significant interaction. Moreover, qualitative analysis (of both data from open questions in the questionnaire and from interviews and focus groups*)* suggests that the actual situation of practicing collaboration is rather more complex. Here, the attitude of everyone to question their own beliefs is considered as a necessary premise for a fruitful collaboration.

Another main issue emerging from the surveys is connected to structural barriers towards the improvement of science education that are characteristic of the national school organization. Among these barriers the more recurrent ones are the organization of teachers' work (mainly in terms of timetables), the lack of material resources, the lack of recognition and incentives, and the large number of students in the classrooms.

Interaction with school administrators is another point on which it is interesting to focus. Here, it is interesting to compare teachers' and principals' perception about structural issues. In both cases, a general perception of a strong lack of material resources emerges, with special reference to the lack of laboratorial facilities as crucial factor for the improvement of science teaching.

In all countries, principals also lament the lack of teachers' adequate preparation in scientific contents and teaching methodologies, together with the lack of motivation among teachers, which is seen as a factor opposing the implementation of innovation programmes. Teachers are seen as using out-of-date teaching approaches, mainly based on the use of textbooks as the main resource. The structural need for a better selection of teachers is connected to the limitations to their decision-making power.

The little relevance attributed to changes in assessment criteria (b.) is mainly correlated to negative perceptions of standardized evaluation tests. Indeed, a particular aspect in all stakeholders' perceptions – not only in the one of teachers – about the impact of official guidelines is connected with the introduction of standardized procedures for the assessment of learning, which is quite a topical issue in recent school reforms worldwide. There is almost general agreement in teachers' negative perception of this kind of tests as long as they expose to the risk of shifting the focus of teaching/learning towards the achievement of good results in the tests.

Tensions between science education research and teaching practice

In teachers' perspectives, the strong need expressed for the circulation of ideas and resources for the improvement of science teaching often refers to the importance of exchanging experiences with colleagues, seen as a means for collective growth. At the same time, from the questionnaires a judgement of poor relevance emerges for what regards the involvement of external actors. This is expressed by the large majority of the teachers in the sample (see Fig.1) (c.). This perception is again in line with the strong relevance of "professional experience" as source of important ideas for science teaching emerging from answers to Q1.

Putting all these considerations together, a picture emerges of teachers having strong confidence in their personal teaching skills. On one side, this could imply that teachers are interested in carrying out research autonomously in their schools, as is suggested by the fact that many among both teachers and other stakeholders in our small-scale sample referred to school as the place where research in science education has mainly to be carried out. Another possible interpretation, though, might be that that teachers see research finding mainly as teaching materials produced by research professionals they can profit from and use autonomously at school.

A finding that emerges clearly in all national surveys is that teachers would like to receive greater support from universities in order to improve their teaching practice. In teachers' answers to open questions in the questionnaire, and in interviews and focus groups, contact with research was frequently depicted as 'rare' or 'not common', while need was express for a stronger interaction between school and university. In fact, many teachers in our sample referred to research as a relevant transformational tool in their practice in the classroom, as it implies a direct impact on student learning. This is also confirmed by quantitative data on the relevance of enhancing "connection between practice and research" as a priority action in order to improve science education emerging from teachers' answers to Q8 (see Fig. 1). Nevertheless, we think deeper understanding is needed of the kind of contributions teachers expect from the interaction between school and university. At the same time, indeed, teachers often underestimate direct interaction with science education researchers, as is also evident from answers to Q8.

The reasons that are mentioned with highest occurrence refer to researchers' attitudes. Teachers depict researchers as lacking the capacity to actually manage the work in the classroom, mainly in terms of mediation strategies. Despite providing an important and necessary contribution in terms of disciplinary contents, researchers are seen as not having the necessary 'sensibility' for what concerns the dynamics of interaction and work with children. Moreover, one of the main and most widespread critical knots in the relationships between teachers and researchers seems lie in the teachers' vision that researchers are not sufficiently aware of school contextual matters and related constraints. Many teachers in our sample said researchers come to school in order to collect data for their publications and that scarce feedback is given for the school to actually be able to profit from.

When teachers refer to the importance of connecting their practice to the research evidence, they point out that their main interest seems to be directed towards educational tools and resources they can use autonomously.

By their side, researchers see the lack of interest towards collaboration as related to teachers' resistance towards didactic experimentation: teachers adopt innovation contributions only in very special situations, because experimentation leaves less room for the usual implemented curriculum, which is well inserted in the overall system and regulated by many factors, such as higher grades standards or internal surveys.

Moreover, it seems that some topical themes of research in science education play little role in teachers' interests. Generally, teachers underline the necessity to root practice in inquiry-based activities and to increase the material resources therefore necessary (d.). More precisely, many teachers mention the necessity of basing science education activities upon “practical work” and underline the importance of increasing the material resources devoted to this kind of activity. Nevertheless, a widespread view is that laboratories are a special context in which non-ordinary activities can be carried out. The whole idea of good practice in science education seems to be centred on the necessity of ‘practical’, ‘experimental’, ‘lab’ activities. These connotations are recurrent both in answers to open questions in the questionnaire and data from interviews and focus groups. The vision good practice appears indeed to be weakly connected with an inquiry-based approach, suggesting a naïve interpretation of hands-on work by the side of the teachers. Experimental activities are described as strongly based on pre-defined procedures, being often reduced to the mechanical repetition of a standardized set of manipulations. They often lacks of the direct participation of the pupils and aim more at obtaining ‘correct results’ than at comparing conflicting explanations or giving answer to any inquiry questions. This finding is in line with research conducted in other countries on science teachers’ belief on and implementation of practical work (see e.g. Millar 2010 and references therein).

Our data also suggest another facet of teachers’ perceptions of science teaching and learning. One that seems more aware of the cognitive aspects thereof. When asked about ‘important ideas about science education’ (Q1), teachers frequently refer to students’ thinking and reflection and when asked about the ‘most important goals of science education’, the majority of them rank critical thinking above learning for becoming a scientist or science for citizenship. In the case of teachers sharing this vision, emphasis is placed on the importance for students to learn to think and explain the way scientists do. Considerations of this kind of are indeed common cross-context and cross-nation in our data. There are although a few teachers who explicitly refer to thought processes that have been treated extensively in research on teaching approaches, like for example significant knowledge or teaching for understanding.

CONCLUSIONS AND DISCUSSION

Our analysis of a large amount of data collected in six countries as different as Argentine, Brazil, Colombia, Israel, Italy and Spain allows us to further detail some crucial open research questions and suggest specific aspects to look at in order to better understand the systemic features of the research-practice issue in science education. Findings emerging from our surveys highlight some of the factors underlying the tensions existing between three key components of the science education scenario: policies, research and practice. While some factors are common to the six countries involved, in other cases deeper insight is gained when comparing issues and strategies to address them in the different contexts. Based on our findings, we propose a research strategy for investigating open issues related to the research-practice gap. We suggest that an effective path is field research involving whole schools regarded as complex systems of interacting dynamics. In these programmes, teachers should be less the target of a ready-made intervention based on assumed research evidence than the protagonists of a participative process in which they work together with researchers as peers at all stages. Our findings sketch out a picture of teachers marked by a strong sense of isolation and scepticism towards policies and external actors entering the school. At the same time, a positive perception of research and innovation and a great need for change clearly emerge. Scepticism is a natural reaction when change is imposed top-down without debate, as is mostly the case of policies in the countries involved in our surveys, or when the interests of those promoting the change (e.g. researchers) are perceived as distant from one's own. Our findings lead us to believe that an in-depth inquiry into factors contributing to school's resistance to change cannot be addressed without an active involvement of those expected to be effected by the change. Based on the findings of our surveys, we have drawn up a set of indications for devising researchers-teachers interactions aimed at implementing research-based teaching (the complete set of indications can be found in D3.1, see above). Our field actions (now almost at the end of their one-year span in over 50 schools) are confirming that building trust is a process of mutual understanding and recognition which is based on a constant dialogue and exchange and participative decision making. That flexible structure and open-ended approach allow for an understanding of teachers' needs and expectations and the factors constraining their everyday practice. That this process is necessarily situated and context dependent as long as acceptance is based on the recognition that actions implemented are relevant to one's own practice. These findings support and widen the idea of "resonance" between research and practice as a key factor for bridging the gap as was suggested by Ratcliffe et al. (2005) and the considerations about essential elements in effective professional development emerging from the CASE project as reported by Adey & Serret (2010). Many of our findings are corroborated by the insights emerging in the framework of TRACES from analyses from other partner countries and presented in the common ESERA symposium. In particular, conclusions drawn by Israeli and Brazilian colleagues confirm our vision of the tension among policies, research and practice in science education and the need for a more active involvement of teachers and schools in research and development programmes. The question whether the role of researchers and teachers in common R&D programmes should be firmly distinguished based on the consideration that their competencies are structurally different remained open at the end of the symposium, with researchers from both the symposium panel and the audience holding different positions on the matter.

PRACTISING SCIENCE TEACHERS' VIEWS ON CORES AND ITS IMPACT ON THEIR PROFESSIONAL KNOWLEDGE OF PRACTICE

Adam Bertram[1]
[1]Monash University, Victoria, Australia

Abstract: This paper reports on a research project that explored the use of CoRes with in-service secondary and primary teachers in Australian schools. The two year longitudinal study investigated how these teachers (n = 6) might *value* CoRes, after constructing and using them in their classrooms, and how the instrument might influence or develop their long term professional practice. In particular, the project explicitly explored how their PCK might be articulated, revealed or developed as a consequence. In constructing and using CoRes in their classrooms, all six teachers claimed that the CoRe was a considerably valuable instrument in helping them to frame their knowledge of practice more explicitly, that they began to articulate and form an understanding of their own PCK, and that the CoRe prompted them to meaningful reflect about their practice in more deliberate, conscious and effective ways.

Keywords: Content Representations (CoRes). Pedagogical and Professional-experience Repertoires (PaP-eRs). Pedagogical content knowledge. Science teacher education. Science teachers' knowledge.

BACKGROUND, FRAMEWORK AND PURPOSE

Pedagogical content knowledge (PCK) has long been an attractive construct for educational researchers since its conception over twenty-five years ago (Shulman, 1986). PCK received much attention, particularly within science education research, because it presented a new way of conceptualising, acknowledging and viewing a distinct and specialised form of teachers' knowledge. PCK brought together the idea that, as part of their professional knowledge of practice, the teacher linked content knowledge together with knowledge of pedagogy in sophisticated and complex ways which meaningfully enhanced student learning (Loughran, Berry, & Mulhall, 2006).

While the academic world has engaged in ongoing and largely theoretical discussion about that which encompasses PCK (Kind, 2009), it is difficult to find accounts of its value and use for teachers in practice. Abell (2007) called that more PCK research on teachers in practice was needed: "It would benefit the research if conceptual frameworks were made explicit. … More studies need to focus on the essence of PCK – how teachers transform SMK [subject-matter knowledge] of specific science topics into viable instruction …" (p. 1134). Specifically, within the realm of science education, Van Driel (2008) called for effective ways of developing science teachers' PCK, particularly because "science teachers often have problems to transform their content knolwedge into a form which is appropriate for the specific target group they teach" (p. 1).

In responding to these calls, science education reseachers Loughran, Berry and Mulhall (2006) developed CoRes as one such framework. CoRes were intended to engage teachers actively in the process of learning about their own practice, and in drawing out their tacit practices and expert teacher knowledge in ways that would begin to articulate and portray instances of their individual and unique PCK. Importantly, CoRes deliberately attempted to capture the complex knowledge of the teachers' thinking and reasoning behind and about the content of a specific science content area and the choice of pedagogical activities that would be best suited for their particular students.

In this way, CoRes seemingly offerred a way of conceptualising PCK into a usuable construct into the real world of teacher practice, and therefore offered a new way of viewing the theory-practice gap (Korthagen & Kessels, 1999; Pekarek, Krockover, & Shepardson, 1996). It is hoped then, that as practicing science teachers' use CoRes in their practice, that the theoretical construct of PCK becomes a more explicit, substantive and valued part of their professional knowledge and provides them with a common langaugage in which they can easily share their PCK with colleagues (A. Bertram & Loughran, 2011).

This research study therefore tested CoRes with practicing science teachers ($n = 6$). The main purpose of the research was to explore these teachers' views on using CoRes in their practice. The two year study explored:

- how CoRes might be *valued* by these teachers;
- how the process of creating one and using it in their practice might, if at all, have influenced or developed their professional knowledge of practice;
- if they felt it caputured or portrayed instances of their PCK; and finally,
- how their individual understanding of PCK might have developed as a consequence.

RATIONALE

In the science education research literature, CoRes have been favourably reported on as an effective instrument in capturing and providing reified examples of science teachers' PCK (Kind, 2009). Yet few studies exist where they have been tested and validated with practicing teachers. This study takes the important step of "testing for applicability" in the classroom and seeks to validate or test CoRes with practising science teachers over a two year period.

METHOD

This research involved six practising teachers in a longitudinal, ethnographic study (cf. A. R. Bertram, 2010). At the start of the study, the teachers were individually interviewed and asked to describe their current views on teaching and learning. The construct of PCK was then explained to the participants and they were introduced to the framework of CoRes. Participants were then expected to develop and produce their own CoRe based on a science unit or topic that they would soon be teaching. Soon after this stage, the participants were interviewed for comment on the process of making it and how this process might, if at all, have influenced their thinking about teaching and learning, and in particular, how it might begin to reveal and/or develop aspects of their own PCK.

In due course, participants taught the topic or content on which their CoRe had been based. Again, participants were interviewed to explore their views on the impact, if any, that the CoRe might have had in the teaching of the topic. About a year later after using the CoRe in their practice, participants were interviewed to provide their post-intervention views on teaching and learning. These views were contrasted with their pre-intervention views and participants were asked to consider if any changes might have been influenced by using the CoRe in their practice. This final interview also considered the participants views' on the long-term impact or influence which CoRes might have had on their professional practice, and in particular, how they might have, if at all, developed their own PCK.

The major source of data collection for this study came from individual interviews at each stage of the research. The open interview format allowed teachers to offer narrative accounts which enriched the data and provided great insights into their thinking (cf. Clandinin & Connelly, 2000; Conle, 2003). However, a weakness of the reliability and validity of this methodology might be that much of the data relies on self-report. Therefore some degree of triangulation was embedded into the research design to limit these weaknesses and to provide credibility. The teachers' CoRe itself became a data source which was used to reinforce the reliability of the teachers' narrative accounts and the extensive and longitudinal nature of the interviewing process supported the consistency of the teachers' ideas and views over the length of the study.

RESULTS

All participating science teachers claimed and endorsed CoRes as being an effective instrument which helped them to better understand their professional knowledge of practice. On a general level, all participants believed that CoRes offered them a structured and meaningful means of reflection which forced them to reflect in a purposeful and deliberate manner. Individually though, the CoRe each brought out something different about the practice of each participant. For three of the participants, they felt that it made them rethink their general understanding of what "teaching" and "learning" meant to them on a personal level. For three other participants, they claimed that the CoRe impacted the way they understood the term "student learning" and it caused them to think more carefully of how their particular students' understood the content being taught.

All participants (none of which had an understanding of PCK prior to this study) agreed that the construct of PCK, *as developed through their CoRe,* offered teachers' an important and useful construct for shaping their professional knowledge. For the participants themselves, they now had an instrument which had provided concrete forms of instances of their own PCK. All participants believed that by having an awareness of these instances, and in the process of making the CoRe - the deliberate questioning and reasoning about the content and the pedagogy forced by the CoRe's prompts – improved their understanding of teaching and learning and impacted their long-term knowledge of practice.

The researcher also noticed that the teachers, at the post-intervention stage, now had begun to develop a shared language of communicating their PCK and ideas about teaching and learning with others.

While the participating science teachers' views of CoRes support that it is indeed an effective instrument in articulating and developing PCK and that it would be extremely useful for the professional teacher, there was a major limitation to its design. All participants stated that an enormous investment of time was required for its production; and not one of the participants could see themselves using it in their own practice of their own volition. Two participants suggested that perhaps, CoRes be embedded into the curriculum practices of the school.

CONCLUSION AND IMPLICATIONS

This research study provides some evidence that CoRes provoked participants to think beyond their normal approach to practice. It also gave them a vehicle from which they could reframe their views in line with a (developing) PCK perspective. In essence, all participating science teachers' claimed that CoRes positively influenced their professional knowledge of practice and enhanced their understanding of PCK. Hopefully, this study has verified to some degree that CoRes offer a valid means for which the academic concept of PCK may be actualised in practice, thereby reducing the theory-practice gap and presenting exciting new possibilities for research into the important area of that which constitutes practicing science teachers' professional knowledge of practice.

DIAGNOSTIC COMPETENCIES OF PRE-SERVICE TEACHERS ANALYSED BY MEANS OF THE SIMULATED SCIENCE CLASSROOM

Claus Bolte[1], *Georg Koeppen*[1], *Jens Moeller*[2], *Anna Suedkamp*[2]
[1]Freie Universität Berlin (Germany)
[2]Christian Albrechts Universität Kiel (Germany)

Abstract: Pedagogical diagnostic competence (PDC) is one of the main professional skills of teachers. It is a fundamental precondition to identify students' difficulties in learning or their shortcomings in knowledge, which is fundamentally important precondition though a teacher will be able to select appropriate feedback and actions to support the students' learning. Beyond that, the teachers' PDC is the requirement necessary for the fair judgement of students' performances. However, it seems to be difficult to ascertain PDC in the context of teaching, because in authentic teaching situations the influence of confounding variables can hardly be controlled. By employing a specifically adapted computer program – the "Simulated Science Classroom (SSC)" – it is possible to create teaching-analogue situations in which parameters of achievement and motivation of "simulated students" can be controlled systematically. In experimental studies we investigated specific components of "science related pedagogical diagnostic competence (SPDC)" of 80 pre-service chemistry teachers taking over the role of a chemistry teacher interacting with 12 simulated students. The analyses show that the examinees were able to compose an approximately correct ranking of the simulated students' achievements, but the levels as well as the standard deviations of the simulated students' achievements were systematically underestimated by the examinees (in all of the four different experimental treatments we investigated).

Keywords: Diagnostic achievement competencies of (pre-service) teachers, Simulated Science Classroom, Science Learning Achievement, Performance Assessment

INTRODUCTION: BACKGROUND, FRAMEWORK, AND PURPOSE

It is considered extremely difficult to systematically conduct research on diagnosing competency in an educational context, since the number of distracting variables in authentic classroom situations are almost impossible to control. Using a specially developed computer programme, it is possible to simulate classroom-like situations and to systematically control the performance parameters of simulated students. In this way, the classroom situations – albeit that they are simulated – allow for the possibility of using experimental studies to conduct research on pedagogic-diagnostic competencies of (pre-service) teachers regarding their ability to assess the performance of (their) students. – Together with the taskforce "Psychology for Pedagogues" at the University of Kiel, a research group in Freie Universität Berlin's Department of Chemistry Education has developed a set of virtual scenarios which simulate classroom situations in science lessons of grades 5/6.

This article will introduce the development of the computer programme used to simulate these science lessons as well as the first results of our experimental studies with 80 pre-service chemistry teacher students.

RATIONAL – CURRENT RESEARCH

Aside from being able to show the necessary leadership qualities in the classroom as well as pedagogical skills and knowledge of the subject, a teacher's diagnostic competency plays a significant part in the development and success of lessons (Helmke, Hosenfeld & Schrader, 2004). Diagnostic competency is, in essence, the ability to fairly judge a student's performance (Schrader, 2006). However, diagnostic competency can also include the ability and knowledge to enable teachers to appropriately make these judgments – amongst others methodical knowledge (e.g. knowledge and command of diagnostic methods, knowledge of judgment errors and tendencies) and subject-specific knowledge (e.g. the expectations in a specific area of learning or the difficulties of certain tasks). On top of that particular awareness plays a significant role (e.g. awareness of particular students and classes, e.g. their strengths and weaknesses and the difficulty and popularity of particular subject areas in these classes).

Previous research on teachers' diagnostic competency has focused primarily on the accuracy of diagnostic assessments of written tests. Studies compared teachers' assessments as regards different student traits with the "actual traits" – surveyed using standardised tests. The interpretation of the data is usually restricted to a measure of congruence – correlating calculations between teacher assessment and trait manifestation. According to Helmke and Schrader (1987), three components must be considered when analysing the accuracy of teachers' assessments:

- the *level*,
- the *differentiating* and
- the *rank component*.

The *level component* is a measure of the assessment of the absolute level of a student trait. The *differentiating component* shows whether dispersion of the student trait has been overestimated or underestimated. Finally, the rank component determines whether within a particular class the teacher has correctly determined a rank of the students' performances.

Until now, only few studies on the diagnostic competency of teachers considered all three of these components of diagnostic assessment. If the level of a student's performance is taken into consideration when investigating the accuracy of performance assessments then the results often show an overestimation of student performance (Artelt, Stanat, Schneider & Schiefele, 2001; Bates & Nettelbeck, 2001; Madelaine & Wheldall, 2005). On the other hand, there is usually an underassessment of the dispersion of student performance (Helmke et al., 2004; Helmke & Schrader, 1987), while the rank component is reported as satisfactory (Demaray & Elliot, 1998; Egan & Archer, 1985; Feinberg & Shapiro, 2003; Hoge & Butcher, 1984).

According to this, teachers assess the rank of student performances relatively well. But, all the aforementioned studies focused on the analysis of test subjects' diagnostic qualifications, as determined by written data of student performance (e.g. written tests or examinations).

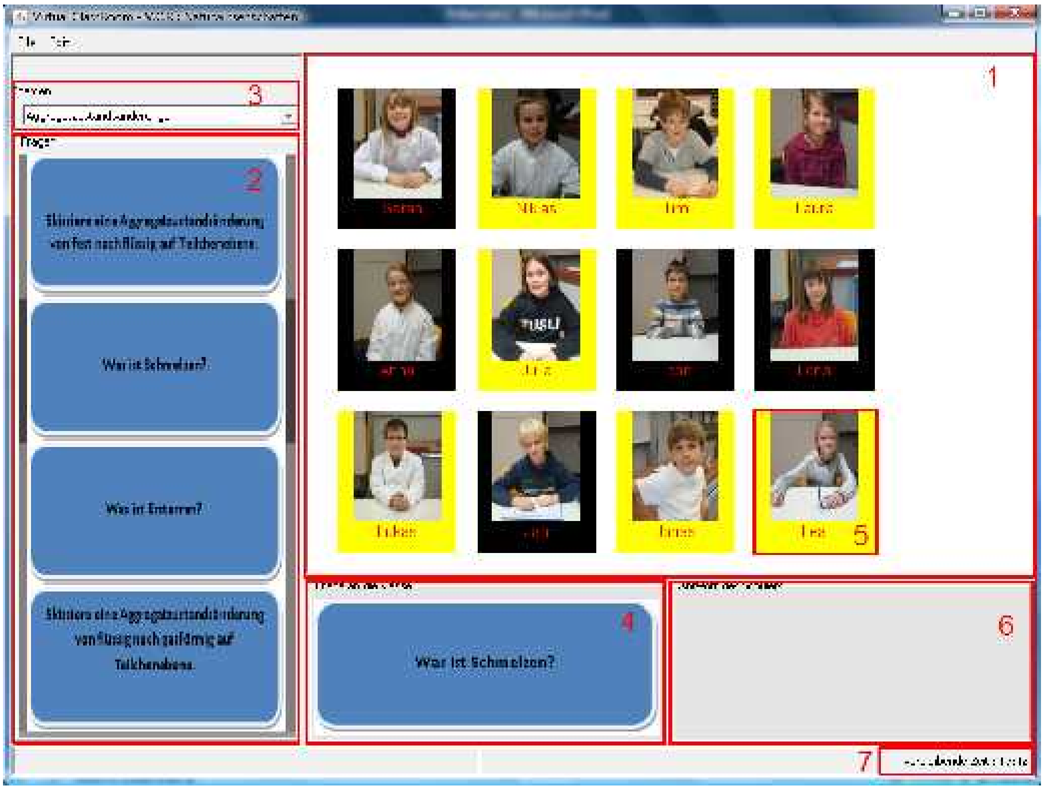
However, *how is the diagnostic competency of the (budding) teachers affected when the assessment of student performance is solely based on their oral participation in class as this is the case in most school learning situations?*

Scientifically, this question has proven difficult to answer.

METHODS

The Simulated Classroom (SCR)

The paradigm of the simulated classroom is a method well suited to experimentally investigate diagnostic competency (Fiedler, Freytag & Unkelbach, 2007; Fiedler, Walther, Freytag & Plessner, 2002). The method comprises a computer simulation of a classroom, in which the user (examinee) takes on the role of teacher and proceeds to interact with virtual students (see picture 1; no. 1); leading to the assessment of experimentally steered student performance, for example.



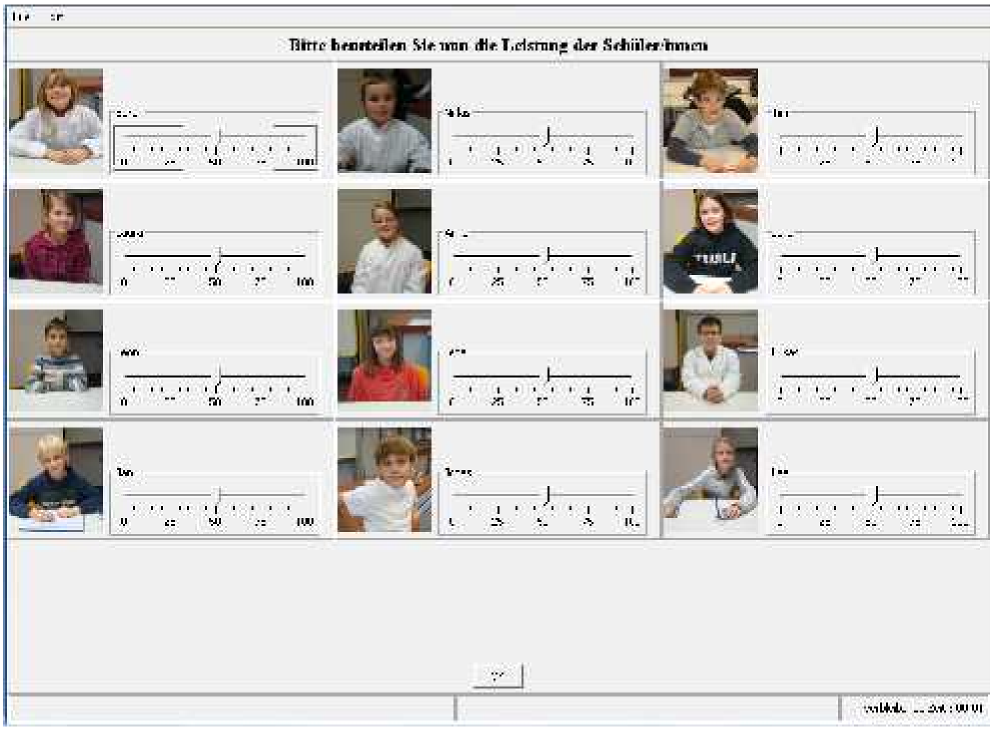
Picture 1. Screen of the simulated (science) classroom

During the Simulated Classroom settings the examinee chooses subject specific test questions (see picture 1; no. 2) from a list f topics and contents (see picture 1; no. 3) and directs them at the simulated students (see picture 1; no. 1). The selected question appears on the screen (see picture 1; no. 4). Now, some of the simulated students (pictures) appear in a yellow frame symbolizing that these students show up to give an answer (see picture 1; no. 5) to the selected question (see picture 1; no. 4). These yellowed framed simulated students can be asked by the examinee to give the answer. The student answer than appears and is to read in the “answer-frame“ on the screen (see picture 1; no. 6). This answer will be a correct or an incorrect one which is to recognize by the examinee reading and assessing the student answer (and/or by looking on the picture background of the answer which is green in the case of a correct student answer or red in the case of an incorrect respond).

This procedure can be repeated and is to repeat till the simulated lesson is over; in our study a simulated lesson takes 18 minutes. Last but not last, the examinee can see the remaining lesson time of the simulated lesson by means of the “time-frame” (see picture 1; no. 7).

After the simulated lesson the examinee has to assess the performance of each student, first on a scale from 0 to 100 and last but not least by a six-point-rating-scale.

The number of correct answers by the individual simulated student represents his/her performance ability. The performance parameters of the simulated students are selected and fixed by the examiner before the testing of the examinees and – of course before – the investigation of their ability to assess the simulated students' performance.



Picture 2: Screen of the students performance assessment in the simulated (science) classroom

The correlation between the students' performance and their assessments by the examinees can be interpreted as the diagnostic competency of the examinee-sample.

The simulated classroom can act as a tool for the experimental investigation of different questions with regard to teacher, student and classroom research. Apart from the students' performance abilities, a wide range of other student traits (such as motivation skills, social interaction, socio-cultural background) can be simulated and investigated regarding their effects in teachers' assessment processes. This is particularly interesting when looking to conduct research on different and specific diagnostic competencies. Nevertheless, the overall aim should be to portray the classroom situation as socio-ecologically valid as possible, while at the same time allowing the investigation of experimentally exaggerated questions with high internal validity.

The Simulated Science Classroom for Years 5/6

In the course of adapting the programme to incorporate science educational research, the working group agreed on first concentrating on science classes grades 5 and 6 (in German: Naturwissenschaften 5/6). The questions and the anticipated right and wrong student answers, which were developed as part of this project, have been taken from other empirically tested instruments. By means of these instruments students' conceptions and misconceptions concerning specific science concepts (e.g. the particle model of matter or concepts of inquiry) were analysed (Benedict & Bolte, 2008; Erb & Bolte, 2009). The analysed student answers build the basis for the stimulated student answers in the simulate science classroom (see picture 1).

The research question of this – as far as we know – first science educationally weighted study is:

In how far are (budding) chemistry teachers able to assess and judge student performance in the lesson correctly?

The simulated classroom of science classes in grades 5/6 was designed and realized in two different versions. In this publication we will focus only on introducing the results of the version that ignores the influence of the subject content knowledge of the examinee. This concentration on only one treatment version has been chosen for better comparability with the setup of the previous studies we are referencing at (Spinath, 2005; Südkamp & Möller, 2009; Südkamp, Pohlmann & Möller, 2008).

Furthermore, aside from the three assessment components mentioned above (see level, differentiating and rank component) a fourth component, the global degree of variation component – developed and introduced by Südkamp (2010) – will be included in our analysis.

Two questions (which are more methodological in nature) form the core of our experimental study:

1. Are there statistically significant differences in test subject performance (here: chemistry teacher students) in terms of the four selected assessment components between the examinees in this study and those examinees of other studies which were conducted with the help of the simulated classroom? (effect of the subject and the students PCK pedagogical content knowledge)
2. What are the differences in the examinee' diagnostic performance between test run 1 and 2, if they are asked to complete two test runs with the help of the simulated classroom for science in grades 5/6? (training effect)

RESULTS

First Investigations Using the Simulated Classroom

In first investigations using the simulated classroom (SCR) conducted by the working group of the taskforce "Psychology for Pedagogues" at the University of Kiel, Südkamp and Möller (2009; see also Südkamp, Pohlmann & Möller, 2008) were able to show evidence regarding the instrument's validity (Südkamp, 2010). Furthermore, the teacher students they investigated by means of the SCR were able to form a rank of student performance within a class. However, the absolute level was overestimated by the Kiel examinee, while the dispersion was underestimated by them.

Results from the Study using the Simulated Classroom of Science in Grades 5/6

In the research context of science education a sample size of 20 chemistry teacher students was used for the first test run. The results regarding question 1 and 2 are listed in Table 1.

	Bolte et al. (2010)	Spinath (2005)	Südkamp et al. (2008)	Südkamp & Möller (2009)
Rank component	0,40; 0,26	Median: 0,40	0,62; 0,68 0,54; 0,53	0,64; 0,66
Level component	-0,07; -0,09	0,03	0,04; 0,03 0,09; 0,07	0,07; 0,09
Differentiating-component	0,79; 0,71	0,84	0,76; 0,92 0,74; 0,81	0,81; 0,82
Global degree of variation	0,17; 0,19	./.	0,20; 0,15 0,21; 0,20	0,20; 0,19

Table 1. Results of the analysis of diagnostic competency – differentiated by assessment component and (reference) study

CONCLUSIONS AND IMPLICATIONS

In our opinion, the results obtained with the help of the simulated science classroom grades 5/6 are comparable to the results obtained in the reference studies. Noteworthy is the fact that with regard to the results of the rank component, the examinees of the science educational study do not quite reach the level of the examinees in the reference studies. Striking is the drop in performance of the chemistry teacher students (examinees) in the second test run. Interesting and worth mentioning is also the finding that the examinees of the science educational study underestimate the performance level of the simulated students – to our knowledge this effect has not been shown in other studies before.

Further investigations conducted by Bolte, Köppen, Möller and Südkamp should and will show whether these peculiarities and potential discrepancies are a coincidence or whether they have systematic causes (Bolte, Köppen, Möller and Südkamp, in process).

Abstract: This Proceeding will explore the theoretical underpinnings of the construct of PCK as researchers are currently using it. Five speakers will provide perspectives on the overall problem; the theoretical conceptions, measurements, and results used within specific research groups; and provide a synthesis of the research while engaging the audience in discussion.
To consolidate different point of views on PCK, we have selected researchers who use more qualitative methods such as interviews and open-ended questionnaires as well as researchers using more quantitative methods, such as open-ended and multiple-choice items for large-scale paper-and-pencil-tests. This symposium will also be interdisciplinary, connecting biology, chemistry, and physics PCK research, thus shining a rare spotlight on PCK in the natural sciences.

Keywords: Pedagogical Content Knowledge, qualitative methods, quantitative methods, natural sciences

DEVELOPMENT OF THE CONSTRUCT PEDAGOGICAL CONTENT KNOWLEDGE

Background

Teachers' professional knowledge may be considered the single most important characteristic in instruction. Elbaz (1983, p.11) points out that "the single factor which seems to have the greatest power to carry forward our understanding of the teacher's role is the phenomenon of teachers' knowledge." To categorize this knowledge, Shulman (1987) distinguished seven categories: content knowledge; curricular knowledge; pedagogical content knowledge; general pedagogical knowledge; knowledge of learners and their characteristics; knowledge of educational contexts; and knowledge of educational ends, purposes and values. Ever since Shulman established these categories, many researchers have come to believe that pedagogical content knowledge (PCK) is an important topic in science education, and that high levels of PCK will predict high levels of student achievement (Abell, 2007). However, research has not yet produced a general consistent model or measuring method of PCK (cf., Park & Oliver, 2008; Fischer, Borowski, & Tepner, in press).

In recent research there are two different approaches to model PCK. Some researchers see PCK as was introduced by Shulman: an integrative knowledge category (Gess-Newsome, 1999). This view of PCK includes an 'amalgamation' of other knowledge categories (e.g., content knowledge and general pedagogical knowledge [Shulman, 1987]) with a particular inner knowledge part.

Using this definition of a PCK model, Baumert et al. (2010) showed a high correlation between PCK and content knowledge, even though content knowledge and PCK are separate categories that can be empirically distinguished.

From another point of view, PCK can be seen as a separate category of knowledge with its own unique identifiers (cf., Magnusson, Krajcik, & Borko, 1999). These models are called transformative models of PCK (Gess-Newsome, 1999), because in these models, PCK can be seen as a transformation of knowledge from other knowledge categories (e.g. knowledge of science curricula, understanding of science, instructional strategies and assessment of scientific literacy [Magnusson et al., 1999]). Both approaches to PCK models agree that the knowledge of representations of subject matter and instructional strategies incorporating these representations, and additionally, the understanding of specific student conceptions and learning difficulties are important facets of PCK (Park & Oliver, 2008).

Numerous methods of measuring teachers' pedagogical content knowledge have been developed since Shulman introduced teachers' pedagogical content knowledge: interviews, paper-and-pencil tests for theoretical knowledge, paper-and-pencil and video vignettes for reflective knowledge, teacher training as an intervention and video observation of real instruction, and, very commonly, a combination of two of these. The research studies using these methods can be divided into two groups: small-scale and large-scale assessments.

In small-scale studies, paper-and-pencil tests and a quantitative analysis of video observations cannot be used because psychometric criteria cannot be achieved. On the other hand, in large-scale studies, intervention and interviews cannot be used because the workload is too much.

At the beginning of PCK research intervention, an observation or intervention and interviews were used to investigate PCK in small-scale studies (cf. Lee & Luft, 2008, van Driel, Verloop, & De Vos, 1998). The aim of these studies was not to measure PCK, but to validate models of PCK (cf. Park & Oliver, 2008). Recently, more quantitative studies have been accomplished based on these small-scale studies. More generalizable results about PCK and the connection to other knowledge categories, as well as the connection to the students' outcomes were and will be produced in these large-scale studies (cf. Baumert et al., 2010). A result of the large-scale studies is, for example, that teachers with a higher PCK score create better lessons, which has a positive effect on the students' content knowledge test results. (Baumert et al., 2010).

So four key divergences in the PCK literature exist:

Nature of PCK: What assumptions exist for PCK as an attribute of teachers? Is it an unalterable characteristic or does it changes with experience and/or particular kinds of preparation or professional development?

Model of PCK: How is PCK related to the professional knowledge base for teaching? Is it transformative or integrative?

Measurement of PCK: Is PCK a knowledge base, an artifact of practice, or both? What are the appropriate levels at which to measure PCK? Should it be examined at the topic level (e.g., mechanics) or the domain level (e.g., physics)?

Contexts for Studying PCK: Where should the emphasis of PCK research lie? Should it be studied in terms of the translation of teacher knowledge to practice, or in terms of the relationship between teachers' level of PCK and student outcomes?

The goal of this session is to use these questions to analyze the positions taken by the three research groups while grounded in a broader analysis of the field.

MEASURING PHYSICS TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE (SOPHIE KIRSCHNER, ANDREAS BOROWSKI, HANS E. FISCHER)

Nature of PCK: The aim of the study is to find important components of PCK which have a big impact on the students learning progression and motivation. And after that these components shall be integrated in the education of student teachers. So the assumption of the study is that PCK can increase with **professional development**.

Model of PCK: Teachers' professional knowledge, which describes the competence in teaching a given subject, has long been recognized in literature as an essential variable for fruitful teaching (Abell, 2007). In order to analyse professional knowledge, it can be broken down into different categories. Recent research (e.g. Baumert et al., 2010) defines three common categories: pedagogical knowledge (PK), pedagogical content knowledge (PCK) and content knowledge (CK). The categories contain many features of Shulman's original seven categories but are differently arranged (Shulman, 1987). PCK is the dimension that only teachers – here physics teachers – have and need. As PCK characterises teachers, is specific for single domains (cf. Park & Oliver, 2008) and is a great predictor of student achievement (Baumert et al. 2010), this presentation will focus on this knowledge category.

Measurement of PCK: In this project, PCK is operationalized as a **knowledge base for teaching** with the help of a three dimensional model. The model covers (1) different knowledge areas, (2) themes and (3) facets.

(1) The knowledge areas are divided into three levels: declarative knowledge, procedural knowledge and conditional knowledge (Paris et al. 1983). The reaction to critical teaching situations can be found in this last area. This was tested with vignettes describing a short situation in a classroom, often in the form of a script. We used some of these for the PCK test, but remain aware of the problem that it is difficult to reliably code the answers and to ascertain that the tested teachers focus on the "right" problem.

(2) The content of the PCK, CK and student tests is mainly related to the topics of **mechanics**, **electricity**, but also contains **physics in general**. Mechanics is part of the curriculum in all German secondary schools.

(3) We use three facets for the PCK test: experiments, teaching strategies and students' preconceptions. Students' preconceptions are important in physics teaching (Duit & v. Rhöneck, 2006) while experiments play an important role in physics lessons. Concepts are a connection between students' preconceptions and experiments: A teacher has to understand physical concepts to decide how to present a topic in a way students can understand it and to avoid deepening their misconceptions. All three facets can be found in the Magnusson model (Magnusson et al., 1999) as knowledge about areas of student difficulty, representations and activities. According to Park & Oliver (2008), it can be assumed that expertise in these facets is important for successful science teaching.

Contexts for Studying PCK: The study is part of a bigger project (Borowski et al., 2010), which investigate the **professional knowledge** of biology, chemistry and physics teachers and its influence on the respective teaching/learning process in class and **the achievement and motivation of students** in science. In the first step the professional knowledge of the teachers is being measured subject related by paper-and-pencils-tests. In the next step teacher knowledge will be measured, their lessons will be videotaped and the science knowledge and motivation of their students will be tested.

Rationale

The COACTIV Study (Baumert et al., 2010), in which mathematics teachers' knowledge was assessed, shows different PCK values for teachers of different school types. The goal of this study is to validate a model, using a related test instrument that has to show on one hand, similar results for in-service physics teachers with similar teacher education (convergent validation), and on the other hand, differences between physics teachers and other groups (pre-service teacher, non-physics-teachers and physicists) who are expected to obtain lower PCK values (discriminant validation).

Methods

PCK was operationalized by using the model described in the section called measurement. The PCK test for physics teachers consists of 17 items. Open-ended and multiple-choice questions were used in the test. The answers were evaluated with a coding-handbook.

N=167 physics teachers located in two different federal states of Germany were tested. Their average age was 44 years (SD=9.9); 29 % were female. The teachers were from different secondary school types in Germany (Bonsen, Bos & Frey, 2008): 137 of them teach at a Gymnasium (GY), 30 at lower level school tracks (NGY). To validate the test, 21 math teachers were tested. The participants completed the test voluntarily in sessions that lasted 50 minutes for this test. They were guided by a supervisor. The entire PCK test has an acceptable Rasch reliability (.76).

Results, Conclusions and Implications

Teachers who did not study or teach physics got poor results, which confirm that the test is able to measure knowledge that is not pedagogical knowledge, general knowledge or abstract thinking. Physics GY teachers were shown to have a significantly higher PCK than teachers teaching at lower level school tracks (NGY), M_{GY}=66.0, SD=15.2, M_{NGY}=44.2, SD=15.8. The significance $p < .001$ was calculated with a T-test, the effect size is large ($d = 1.41$). Of note here is that teacher requirements at different school types in Germany differ widely: Teachers at Gymnasium spend more time at university, and there are differences in the content in teacher education at university, depending on what kind of teacher they are training to become. The results indicate that we are able to measure knowledge that is based on university studies and can be influenced by teacher training. The differences give a first hint that PCK and CK are linked because GY teachers spend more time on learning physics but not on learning pedagogical content.

A valid topic-specific, large-scale paper-and-pencil model for pedagogical content knowledge has been developed. The test, which operationalized the theory-driven model, shows the expected results, which signalizes in sum that we are in fact measuring PCK.

The connection between teachers' test values, their teaching observed by videotaping and their students' knowledge, interest and motivation will be analyzed next. After this, the facets, knowledge areas and topics which are most important for student achievement can be dissected further. In the future, this test can be used to assess physics teachers' theoretical PCK to obtain more generalizable results. These domains will need to be examined in more detail in further studies, which may lead to changes in teachers' education and training and, at a theoretical level, to more focused models for future studies.

CONCEPTIONS OF PEDAGOGICAL CONTENT KNOWLEDGE (JANET CARLSON, JULIE GESS-NEWSOME)

The Nature of PCK: The ultimate goal of teaching is enhanced student learning. We propose that teachers apply two knowledge bases to teaching. The first knowledge bases are academic in orientation. Teachers gain this knowledge through careful study. The knowledge lends itself to measurement through multiple means, including paper and pencil tests. Of Shulman's (1986) proposed **knowledge bases for teaching**, we selected academic content knowledge, knowledge of general pedagogical strategies and skills, and knowledge of the learner as the most relevant to classroom practice. Pedagogical Content Knowledge (PCK) is second knowledge base for teaching. It differs from the academic knowledge bases in that it is **dynamic**, integrates the other knowledge bases, and must be assessed when planning, enacting, or reflecting on teaching.

Model of PCK: PCK is the melding of subject matter expertise with pedagogical strategies and knowledge of the learner to produce high quality classroom practice. PCK is a unique knowledge base held by teachers that allows them to consider the structure and importance of an instructional topic, recognize the features that will make it more or less accessible to students, and justify the selection of teaching practices based on student learning needs (Shulman, 1986). With PCK, neither content knowledge nor generic teaching skills alone are sufficient to be an effective teacher. Our **integrative** definition of PCK includes the sub-components: *Content knowledge* including depth, breadth, and accuracy of content knowledge; connections within and between topics and the nature of science; and fluency with multiple modes of representation or examples of a topic. *Pedagogical knowledge* including a rationale linking teaching strategies to student learning; strategies for eliciting student prior understandings; and strategies to promote student examination of their own thinking; and *Contextual knowledge* including understanding of student variations, such as student prior conceptions, impact instructional decisions

Measurement of PCK: The following assumptions on teachers' professional learning guide our work: (1) Teachers knowledge exists on a **continuum** from weak to strong. (2) Teacher knowledge can be strengthened through preservice preparation programs, inservice professional development, and high quality curriculum materials. (3) Teachers with stronger knowledge bases are better able to improve student learning. (4) Teachers' professional knowledge bases are related to each other, classroom practice, and student learning. (5) PCK is **topic specific** and can vary by topic. A teacher may have high PCK for "carrying capacity" and a low PCK for "protein synthesis." As a result, PCK cannot be effectively determined at the level of "biology."

Contexts for Studying PCK: In our theory of action, we propose that **interventions**, such as professional development, **influence teacher knowledge** bases. These knowledge bases include academic content knowledge (ACK), general pedagogical knowledge (GenPK), and content-specific PCK. We hypothesize that these knowledge bases are related to each other and influence **teacher practice** to become more inquiry-oriented, resulting in greater **student achievement**.

Rationale

The goal of this study was to examine the construct of PCK and how PCK changes in teachers as a result of an intensive professional development and the use of highly educative curriculum materials.

Methods

Our data comes from a study of 40 self-selected high school biology teachers across one state. Participants complete a two-year professional development experience to become familiar with high quality curriculum materials, deepen content knowledge, and expand understanding of effective pedagogy. Over the two years, participants implemented the curriculum, attended five weeks of intensive (40 hours/week) summer professional development, and participated in five days of collaborative lesson study and the examination of student work.

Results

PCK varied by topic. In an analysis of sub-scale MFTB scores at the baseline, percentage correct across the five subscales varied as much as by 61% and as little as 8% (X=32.17%, *sd*=12.77%). When comparing PCK scores across topics using the highest scores in any one sub-topic, scored for an individual varied by as little as 2% and as high as 54% across topics (X=18.42%, sd=11.51%). Clearly, ACK and PCK scores are topic specific.

The *correlation analysis of teacher variables* suggests that they are generally related to one another with most correlations statistically significant. In particular, ACK is not fully distinct from PCK-CK (r = .65, p = .004) but appears to be more distinct than any of the other teacher variables because it is significantly correlated *only* with PCK-CK. In addition, despite being discrete in our theoretical model, PCK-CK and PCK-PK are strongly related (r = .64, p= .004).

Relationships between Teacher Knowledge (ACK, GenPK, PCK-CK, and PCK-PK) *and Teacher Practice* were tested using ordinary least-squares multiple regression. Despite being generally correlated, the teacher variables are not correlated strongly enough with one another to constitute a multi-collinearity problem in the multiple regression analysis. Teachers with higher GenPK and PCK-CK scores exhibited more inquiry-based teaching practices (GenPK, t=3.75, p<.01; PCK-CK, t=2.06, p=.059). No statistically significant relationships were found between either ACK or PCK-PK and Teacher Practice.

Student achievement scores increased significantly from pre-test to post-test for all subscales. We used hierarchical linear modeling (HLM) to *determine the amount of variance in student achievement scores accounted for by teacher knowledge bases and practice* in Years 1 and/or 2. Only teachers' ACK accounted for a significant amount of the variance in student achievement (t=2.18, p=.054). The relationship between Teacher Practice and Student Achievement was not statistically significant, indicating that Teacher Practice is not a mediator of any of the teacher knowledge bases.

Discussion, Conclusions, and Implications

Participants made positive and significant gains in all of the knowledge bases across the program. While there was not a relationship of ACK to teaching practice, increased ACK was associated with greater SA. PCK-CK increased from the baseline to later time points in the program and was positively and significantly related to classroom practice but not SA. These results are complicated to interpret when compared to other studies. When ACK is measured through proxies such as courses taken and grade point average, the relationship to SA is less than 1%. Direct measures of ACK have positive and significant relationships to SA (Baumert et al., 2010; Hill et al., 2005), as supported by this study.

In Baumert et al. (2010), ACK was related to PCK-CK, as was the case in our study, and PCK-CK had a positive impact on SA in their study while in ours it did not.

While increases in GenPK and PCK-PK over the project are supported by our data, the impact of this knowledge on practice varies, with a positive and significant impact from Gen PK but a non-significant impact from PCK-PK. Neither GenPK, PCK-PK, nor Teaching Practice was significantly related to SA. The results may be explained by the mechanical implementation of the curriculum and school-based variables, including testing, that detracted from the implementation of new inquiry-oriented practices.

When considering PCK, the teachers in our study claimed that all parts were important. While ACK laid the foundation for teaching, growth in PK was perceived to be stronger during the project. Our quantitative data supports growth in all areas, though only GenPK and PCK-CK had a significant impact on teacher practice. While we would have hoped to see a stronger impact of the knowledge of student learning (PCK-PK) on classroom practice, this is an area that teachers' admitted to having limited knowledge of and experience with, and it represented a dramatically new way of thinking about their teaching.

DEVELOPMENT OF EXPERIENCED SCIENCE TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE (INEKE HENZE, JAN VAN DRIEL)

Nature of PCK: While PCK has been a subject of research since the 1980s, and much has been written about its importance as a foundational knowledge base for teaching, little is known about the process of PCK development, especially in experienced teachers and in the context of educational innovation. Up to now, few empirical investigations have been conducted into how different aspects of this knowledge are connected and may **influence each other's growth**.

Model of PCK: In the present study, we defined an PCK as teacher knowledge about (a) instructional strategies concerning a specific topic, (b) students' understanding of this topic, (c) ways to assess students' understanding of this topic, and (d) goals and objectives for teaching the specific topic in the curriculum. In this, we largely followed the categorizations of Grossman (1990) and Magnusson et al. (1999, p. 99). Compared with Shulman's original construct (Shulman, 1986), these authors adopted a somewhat broader definition of PCK. Acknowledging that the various components of teachers' PCK may interact in very complex ways, Magnusson et al. (1999) claimed, "Effective teachers need to develop knowledge with respect to all of the aspects of pedagogical content knowledge, and with respect to all of the topics they teach" (p. 115). So the study has a **transformative** view on PCK.

Measurement of PCK: This study focused on the relationship between parts of teachers' PCK and their experience in teaching PUSc. So in this view PCK is a **topic specific** knowledge base for teaching that can expand for each topic.

Contexts for Studying PCK: The study investigates the **translation** of teacher knowledge to practice. For that we followed nine teachers for a period of three years in their natural settings to see if, and how, their initial PCK developed while they were teaching a new subject. The innovation in this study concerned the introduction of Public Understanding of Science (PUSc.) as a new science subject in secondary education in the Netherlands. Among its other objectives, the new syllabus is intended to make students aware of the ways in which scientific knowledge is produced and developed.

Students should gain a clear understanding of a scientist's activities, for example, designing and using models, developing theories, and carrying out experiments (De Vos & Reiding, 1999).

Rationale

The aim of this study was to investigate the developing PCK of a small number of experienced science teachers in their first few years of teaching the new syllabus on Public Understanding of Science. We aimed to identify the content and structure of their PCK of a specific topic in the PUSc. syllabus, namely, 'Models of the Solar System and the Universe', describing its development in terms of relations between its different components (Magnusson et al., 1999). We did not intend to describe in detail the PCK development of each individual participant, but to identify possible common patterns across the knowledge development of different teachers (Verloop, Van Driel, & Meijer 2001).The following research question was central to the study: How can science teachers' PCK of the specific topic of 'Models of the Solar System and the Universe' in the PUSc. syllabus be typified at a time when they still have little experience of teaching PUSc., and how does this PCK develop when teachers become more experienced in teaching this particular topic?

Methods

The study was conducted among nine PUSc. teachers working at five different schools. The nine teachers responded to a written invitation we sent to ten different schools using the same teaching method. The teachers varied with regard to their backgrounds, years of teaching experience, and original teaching disciplines. Among the participants were three teachers of physics, three teachers of chemistry, and three teachers whose original discipline was biology. Their teaching experience ranged from 9 to 24 years at the start of the study. To become qualified to teach the new science subject, the teachers had taken part in a one-year course, which was conducted nationwide. They were all among the first PUSc. teachers at their schools.

With all teachers, a semi-structured interview was held in three subsequent years, immediately after the teaching of a chapter on the solar system was finished. The interview questions were developed on the basis of the results of a study of the relevant literature on PCK, on the one hand, and models and modelling in science and astronomy education, on the other hand.

Results

As a result of the analysis of the interview data from the first year, we identified two types of teachers' PCK of 'Models of the Solar System and the Universe'. These two types were considered as different starting points for the development of teachers' PCK in subsequent years. Type A of PCK appeared to be focused mainly on model content, while Type B of PCK was focused on model content, model production, and thinking about the nature of models. We compared the answers and reactions of the nine teachers with the characteristics of Type A and Type B, and as a result we considered the PCK of five teachers to be more or less indicative of Type A, while the PCK of the other four teachers was classified as representative of Type B. Type A could be typified as mainly oriented towards the teaching of science as 'a body of established knowledge', while Type B could be typified as more oriented towards the teaching of science as 'experiencing science as a method of generating scientific knowledge' (Hodson, 1992).

From our results, we conclude that in the development of PCK of Type A, some of the elements of PCK (especially knowledge about instructional strategies) become more sophisticated or expanded, however, the interaction between these elements was rather static. With regard to the development of PCK elements of Type B over the years, we conclude that changes in the knowledge about instructional strategies, the knowledge about students' understanding, and the knowledge about assessment were mutually related. Teachers' knowledge about goals and objectives of the learning and teaching of 'Models of the Solar System and the Universe' did not change significantly, that is, not only the visualization and explanation of phenomena were still emphasized in this PCK element, but also how to formulate and test hypotheses, and how to obtain information about phenomena.

CONVERGENCES AND DIVERGENCES IN THE CONCEPTUALIZATIONS OF PCK

Current Divergences in the Study of PCK

Frustrated by research findings that revealed weak or inconclusive links of teachers' content knowledge to student achievement, Shulman (1986) proposed a "missing paradigm" in educational research, pedagogical content knowledge. PCK challenged past practices of examining knowledge of subject matter and pedagogy separately. Instead, PCK recognizes the melding of subject matter expertise with pedagogical strategies and knowledge of the learner to produce high-quality classroom practice. PCK is a unique knowledge base held by teachers that allows them to consider the structure and importance of an instructional topic, recognize the features that will make it more or less accessible to students, and justify the selection of teaching practices based on student learning needs. With PCK, neither content knowledge nor generic teaching skills alone are sufficient to be an effective teacher.

Nature of PCK: Until very recently most PCK research has been devoted to describing strong instances of the construct using qualitative research methods (Research Group 3). Such studies have focused on the characteristics within and between teachers. As these studies do not directly address the origins of teacher PCK, or assumptions made about those origins, some reviewers of this research may draw the conclusion that PCK is an inherent characteristic that teachers either possess or do not possess. Other research efforts build on the recognition that classroom practice has a major impact on student success, and rely on the assumption that teacher actions result from teacher knowledge and beliefs (Research Groups 1, 2, and 3). From this foundation, additional hypotheses follow: PCK exists on a continuum from weak to strong, PCK can be strengthened, and teachers with strong PCK are better able to improve student learning. There is mounting evidence that PCK exists on a continuum, both across and within teachers, and influences teaching practice. Working from the assumption that depth of content knowledge is a precursor to PCK, early studies examined the differences between teachers. Some examined teaching practice resulting from different teacher preparation programs (Research Group 1). These studies demonstrated that depth of content knowledge resulted in differing teaching practices, providing initial support for the PCK construct. When examining the development of PCK over time, the results are mixed. Early studies show that PCK develops with the experience of teaching a topic multiple times. Research Group 2 and 3, when studying the impact of professional development on PCK, reinforces this work. Examining student work or elucidating misconceptions are particularly effective means of increasing teachers' careful consideration of content and pedagogical knowledge on classroom practice.

Model of PCK: Building from earlier work and applied to the field of science, Magnusson, et al. (1999) developed a model of PCK. PCK included orientations to teaching (such as inquiry, didactic, and conceptual change) that shaped and were shaped by knowledge of science curricula, knowledge of student understanding of science, knowledge of instructional strategies, and knowledge of assessment of scientific literacy. This model of teachers' professional knowledge defines PCK as a separate and distinct knowledge base with its own unique identifiers. Gess-Newsome (1999) termed this model transformative, meaning that PCK is the product of the transformation of other unique knowledge bases for the act of teaching. In this perspective, the characteristics of PCK such as teacher orientation to teaching science, knowledge of science curricula, and so forth, are transformed into a new knowledge base defined as PCK. This PCK "inside the box" is dynamic and less prone to sub-categorization. For researchers examining PCK from this framework, PCK can often be defined as almost anything that a teacher knows, believes, or can do when thinking about or engaging in the act of teaching. Research Groups 1 and 2 fall into this category. For other researchers, PCK is the integration of the professional knowledge bases, which can be measured individually and within PCK. In this case, PCK is integrative (Gess-Newsome, 1999). Research Group 2 falls into this category. In this case, academic knowledge of content (measured by multiple-choice tests), general pedagogical practices (such as pacing and classroom management), and the ability to list student misconceptions can be contrasted with that knowledge that exists within PCK. PCK is measured through teacher planning, reflection, and practice, and is compared to the other knowledge bases.

Measurement of PCK: The existence of different PCK models has resulted in different tools developed and used to measure teachers' professional knowledge as well as the use of different types of analysis for the data collected. For example, when PCK is considered as transformative, many aspects of PCK can be measured, but they generally culminate in a single PCK measure (Research Group 1 and 3). When PCK is considered as integrative, questions about the relative value of the components of PCK to each other and their relationship to "external" knowledge bases become of interest (Research Group 2). This study was purposeful in identifying attributes of PCK and studying the psychometric properties of the definition. While there is generally a lack of consensus regarding the appropriate level of analysis for PCK, all three Research Groups included in this symposium studied PCK at the topic level. In mathematics, PCK is frequently studied PCK at the domain level - mathematics (Baumert et al., 2010).

Contexts for Studying PCK: Some studies on PCK have focused on the relationship between teachers' PCK and their other knowledge bases and practice. Others have targeted the relationship between teachers' PCK and student achievement. Only Research Group 2 took this approach. The relationship between teacher variables of academic content knowledge, pedagogical knowledge, and PCK is similar to the finding of Baumert et al. (2010). Their results differ in that teacher variables other than academic content knowledge were not related to student achievement. Fewer studies address the contention that teachers with strong PCK are more likely to increase student achievement. Research Group 1 addresses this question by examining teachers in different career stages, working from the assumption that more experienced teachers will possess greater levels of PCK, though student achievement results are not included.

Conclusions and Implications

Research on the nature of teachers' professional knowledge, in general, and PCK, in particular, is a topic of great interest to the science education community. While the past 20 years has generated a wealth of data that has the potential to improve teacher preparation with the goal of increasing student achievement, the variety of definitions and tools for PCK limits our ability to create a strong research base. Conversations across research groups, such as this one, are vital if consensus on the construct is to be reached, or if purposeful variation in the research is to be embraced. This symposium represents an initial attempt to find points of convergence across researchers, and determine fruitful avenues presented by the divergences in research agendas. Our hope is to create stronger synergy in our research definitions, tools, methods, and assumptions so that we might improve teacher knowledge and practice.

THE PEDAGOGICAL CONTENT KNOWLEDGE OF SECONDARY SCHOOL PHYSICS TEACHERS ON ELECTRIC FIELDS

Florentina Cañada[1], Lina Viviana Melo[1], Emilio Costillo[1] and Vicente Mellado[1]
[1]Dept. of Science and Mathematics Education, Faculty of Education, University of Extremadura, Badajoz, Spain. <flori@unex.es>

Abstract: This study examines the initial characterization of the Pedagogical Content Knowledge (PCK) on electric fields of four Colombian secondary education physics teachers. The results revealed four factors that mediate their personal teaching models: their interpretation of the institutional curriculum; the time available to develop the theme in class; the relationship between physics and mathematics; and the consideration of the most effective strategies for teaching physics.

Keywords: Pedagogical content knowledge, secondary school physics teachers, electric field

THEORETICAL FRAMEWORK

For science teachers, the core of their professional development has to be science education itself, since the content to be taught conditions both the teacher's role and the teaching strategies used (Abell, 2007). According to Shulman (1986), teachers develop a body of knowledge about teaching the content – Pedagogical Content Knowledge (PCK) – which is specific to each subject, is elaborated personally in the course of their teaching practice, distinguishes teaching as a profession, and is a form of reasoning and pedagogical action by means of which they transform the content of the subject into representations that are comprehensible to their students. PCK is knowledge that is constructed with its own particular sources, components, nature, filters, and structure (Morín, 1992). From the range of models that describe PCK, the present study assumes that proposed by Friedrichsen et al. (2009) because of the orientations it provides for science teaching, an element that permeates and influences all four components of PCK: knowledge of the curriculum, of instructional strategies, of the pupils, and of evaluation.

Our focus is the topic of electric fields, since this is recognized to be a concept that pupils find hard to learn and understand (Furio & Guisasola, 1997, 1998, 2001; Llancaqueo, 2003). The prevailing teaching itineraries have favoured teaching strategies that proceed from the simplest phenomenology to the more complex (Colombo de Cudmani & Fontdevilla, 1990), i.e., from electrostatics to electric currents, ignoring the part played by the electric field in this transition. Altering this view will involve a profound revision of the teaching models that physics teachers have built up over the course of their classroom practice, both in their initial teacher education and in their professional career. These changes have to start from the knowledge and reflection on what teachers think and do in teaching this concept, combined with their active participation in a process of metacognitive reflection (Mellado et al., 2006)

THE RESEARCH PROBLEM

The research question we set ourselves was: *What is the initial PCK of secondary education physics teachers in Colombia on the concept of the electric field?*

METHODS

The participating teachers were three men and one woman physics graduates, with a mean age of 26 years, and between 3 and 7 years teaching experience. The ages of their pupils ranged between 17 and 19 years.

The study was organized into three phases – documentation, action, and reflection – in which each teacher was to perform a specific task. Each phase was designed as part of qualitative research from a perspective of hermeneutic phenomenology.

The data collection and analysis procedures were: (i) an open choice questionnaire inquiring into what the teacher believes to be the teaching strategies in physics and the role of planning in the teaching and learning process; (ii) the curricular materials the teachers used; (iii) the planning template proposed by Pro (1998); and (iv) the matrix designed by Loughran, Berry & Mulhall (2004) to represent content (ReCo), to which some modifications were made in the number of questions and the form of selecting the core ideas on teaching electric fields.

RESULTS

All the teachers reduced the core ideas proposed for teaching electric fields to electric force, charge distribution, geometric representation of the field, and field intensity. However, they each focused on some subset of these ideas on which they proposed most of their activities.

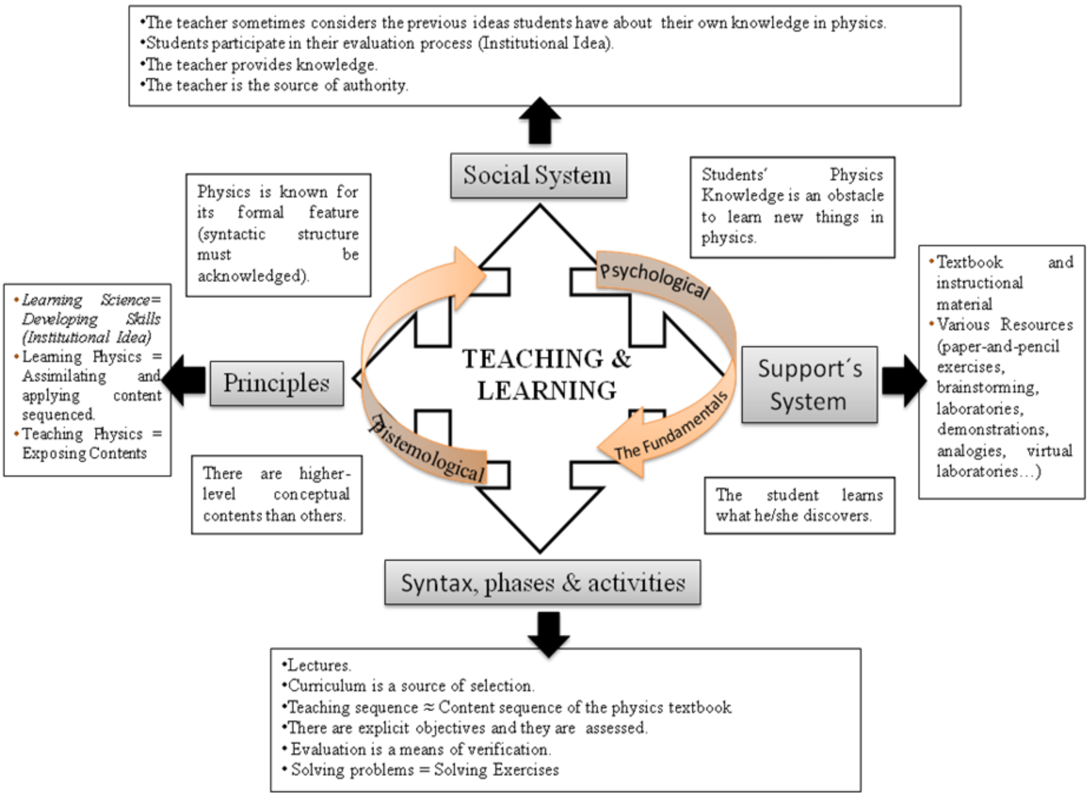
Teacher 1 showed a structure of physics which requires mathematics to be understood. This meant that he emphasized ideas involving the use of algorithms such as the electric force and field intensity, and exercises of application. He also considered that the greatest difficulty the pupils find in understanding the topic is in doing the exercises involving mathematics.

Teachers 2 and 3 focused on the geometrical representation of the field in space, with a view of physics as an interpretation of the world in the form of models. Hence most of the problems or exercises they set had to do with the use and interpretation of lines of force.

Teacher 4 planned his classes around the idea of vector field, as is proposed by the school in which he works. He presents the topic as one more application of this general concept. Although he also presents the idea of physics followed by Teachers 2 and 3, his emphasis in teaching the electric field corresponds more to the idea of physics of Teacher 1. This perhaps reflects this teacher's internal debate between what is required by the institutional curriculum that he has to follow and his own ideas about physics and teaching.

All four teachers centre their teaching on conceptual and procedural content, setting aside in their teaching goals and purposes aspects that are attitudinal or relative to citizenship education. The teachers' stated objectives were both general and specific to the topic. In all cases, these objectives constituted the key criterion mediating the evaluation process, whose character was always as a check of the pupils' learning.

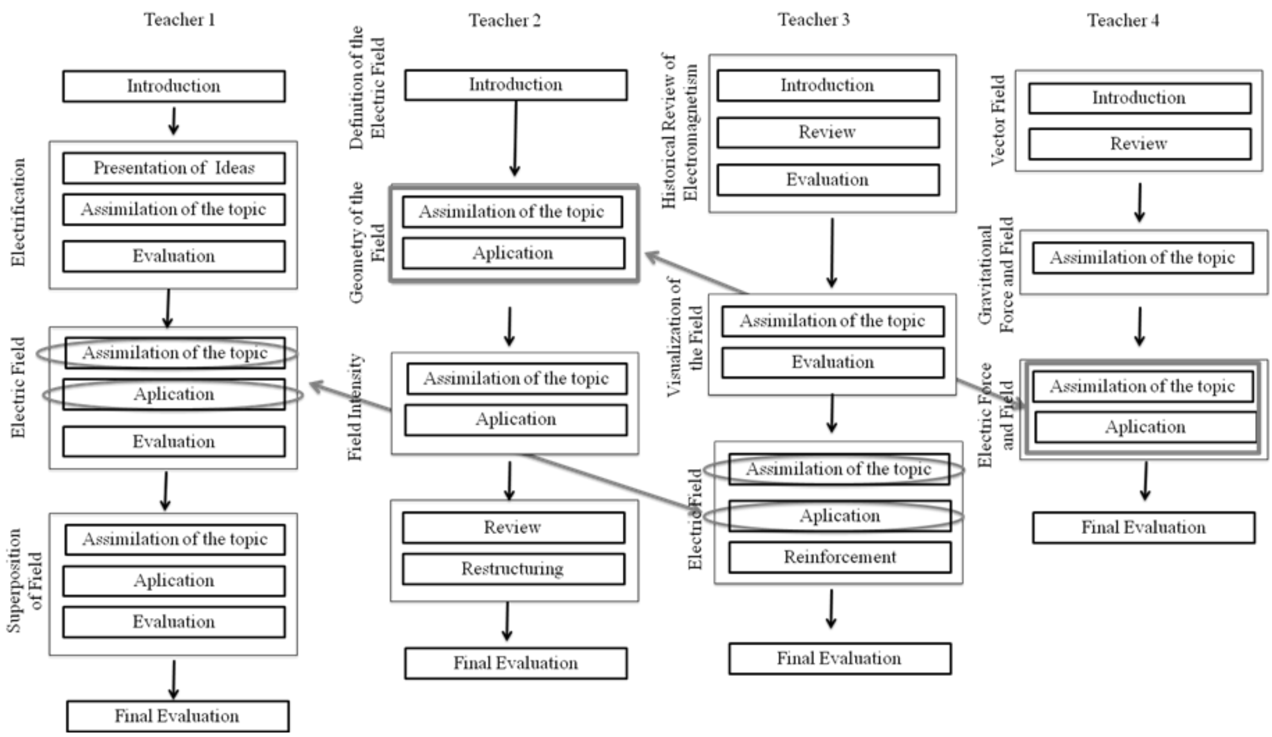
Figure 1: Teacher 1: Teaching and Learning Ideas



The nuances of the traditional model adopted by Teacher 1 (Figure 1) were due to the idea of physics that he fosters together with his role in the classroom. For Teacher 4, it was due to the form in which he implements his school's policies. For Teacher 2, it corresponded to the strong emphasis placed on the time available to work on the topic. For Teacher 3, there was no overriding reason.

The teaching sequences followed by the four participants were extracted from the analysis of instruments (ii) and (iii) (see Methods above). They all proceed by starting with an introduction, followed by a space for the pupils to assimilate and apply the topic, and end with a final evaluation of the unit (Figure 2). The sequences comprise successive blocks which describe how the teacher plans to teach each item of the content linked to understanding the concept of electric field. Teacher 1 repeats microsequences in which the pupil assimilates the subject matter, applies it, and is then evaluated. Teacher 2 prefers blocks in which the pupil only assimilates and applies the topic, leaving the evaluation to the end of the unit. Teachers 3 and 4 use different microsequences for each item of the content. To conceptualize electric fields, all the teachers choose a sequence in which the pupil assimilates and then applies the topic.

Figure 2: Features of the four teahcer´s intructional sequences



CONCLUSIONS

There was a general consensus on which content to teach on the concept of electric field. Teachers 1 and 4 keep to the traditional teaching itinerary used in the university education of physics teachers: they proceed from the phenomena of static electrification until they arrive at the concept of electric field, or they define what a vector field is, and then consider the electric field as a mere application of that definition. Teachers 2 and 3 see physics as an interpretation of the world in the form of models, and consider that the pupils need to visualize the field in order to understand the concept, for which reason they change the order of the content to teach.

All the teachers believed the most effective activities in teaching physics to be pencil-and-paper exercises, the teacher's presentation, and laboratory work, regardless of the teaching and learning paradigm the teacher followed.

The factors which condition their personal teaching models are their interpretation of the institutional curriculum, the time they have available to develop the topic, their ideas on the relationship between physics and mathematics, and their consideration about what is the most effective strategies for teaching physics.

PRELIMINARY STUDY OF TEACHERS´ VIEWS ON SCIENCE EDUCATION IN PRIMARY SCHOOL OF SALTA (ARGENTINA)

Marta Ofelia Chaile y María Cecilia Gramajo
Facultad de Ciencias Exactas – Universidad Nacional de Salta
Argentina

Abstract:

It is presented a progress report with results of a research experience that explores teachers´ thinking about factors that improve and those that threaten good science education in elementary schools in Salta (northern Argentina). Data arise from a survey´s application and interpretation of a questionnaire assumed as an introductory inquiry designed in a more global Research Project (TRACES). A total of 3500 surveys were distributed and a 14% of them answered it. The present report focuses on the answers to questions 6 and 8 of the questionnaire. Conclusions remark specific responses on the pursued factors.

Keywords: teachers´ thinking, elementary school, influential factors, educational research-teaching practice gap

INTRODUCTION

The TRACES Project, Transformative Research Activities. Cultural Diversities and Education in Science, funded by the European Commission under the Science in Society action of the 7th Program, promotes transformative research activities to investigate the factors that contribute to the research-practice gap, with the aim of proposing guidelines for innovative policies in science education that can contribute to fill that gap. In this Project, desk and field research are being combined in a cyclic process of analysis, action, reflection involving both researchers and teachers.

In particular, we are investigating the effectiveness of research based science teaching (Ratcliffe et al, 2005) facing learners' diversities in terms of individual, cultural, linguistic, gender-related factors.

The first phase of TRACES is a field survey to draw a significant picture of all main actors´ perceptions and opinions about the research - practice gap in science education. In each of the partner countries – Italy, Spain, Israel, Argentine, Colombia and Brazil – researchers have developed a 18-item questionnaire applied to teachers of grades 1-10. It focuses on aspects of science education such as availability of resources, interaction among colleagues, pre and in-service training, gender difference, its relationship to research in education. As Ratcliffe et al (2005) say, teachers in science education “recognize and make use of research findings in the course of their normal practice”. In this sense, Jones & Carter (2007) develop a socio-cultural model from which teacher´s beliefs about practice is embedded by perceived social norms when implementing an instructional design. Even though, Lederman (1999) states that “results indicate that teacher´s conceptions of science do not necessarily influence classroom practice”.

Partially based on these findings, present report is part of the survey developed by researchers from the National University of Salta, carried out in northwestern Argentina.

The objectives for the application of the questionnaires are:

a) Recognition of opinions to identify parity or difference between those assumed as critical factors in science teaching arising from the inquiry from those so declaimed by the research literature.

b) Promoting conceptual and strategic hints in relation to public policies and curriculum to take into account in teaching, with the purpose of enhancing science education in primary school.

METHODOLOGY

It is applied a survey protocol (14 questions) adapted from the original format developed by TRACES Project. Local institutional features are considered and adjustments arise from the pilot test realized before the general application of the final instrument. From the total number of teachers of the province (11.174 teachers), the survey is applied to a sample of 3500 school teachers: from the Capital and inner urban, suburban and rural areas; of unique staff school and plurigrade classes' teachers; from state and private schools; teachers who attend lower, medium and high social class´ students, including those coming from native ethnic groups. Responses obtained (478) reach almost 14%. The analysis is made on the answers to questions 6 and 8.

Question 6, *"How positively or negatively influence your teaching each of the following?",* investigates teacher's opinions on the influence of topics from a didactical/professional, socio-cultural and institutional points of view. Referring to specifically didactic issues it is asked on: textbooks, assessment and learning subsunsors. Referring to professional issues it is inquired on training and mastery of content.

Question 8 *"How do you think are the following actions for the purpose of improving teaching and learning science in school?",* investigates topics seen as contributions of teacher's professional practice. Finally, this question aims to recognize the importance of teaching and oriented curriculum policy in a Latin America context.

Questionnaires were distributed by the Post Office service. However, responses were submitted to the will and commitment of School officers and to the interest of the surveyed teachers. Nevertheless, the number of questionnaires received in the mailbox of the Project was really interesting.

The answers obtained were charged into a computational system specially designed for the purpose of collecting and analysis of data.

Following section tables and graphics demonstrate data analysis emerging from research task and its interpretation.

RESULTS

Collected 478 questionnaires, a general overview led to realize a general comprehension of its contents. From this early analysis it was possible to find out a set of categories which allowed classifying the given written answers. One of the main categories is related to didactical issues, the other refers to professional development.

The didactical issues point to teacher´s beliefs about the sense in which resources such as textbooks, teaching materials, experimental equipments, and so on, are effective when teaching science.

The professional development issues point out various ways in which, in teacher´s opinions, science teaching is supported such as pre and in-service training programs, mastery of content, collaborative teacher´s assessment.

Referring to first issue teachers believe that educational factors such as textbook, assessment, subsunsors are mainly influential in science education (63.81% - 77.20%), as it is shown in the following tables.

Category: Didactics - Subcategory: textbooks

Option	Σ	% Σ
None	12	2,51
Very negatively	1	0,21
Negatively	8	1,67
Without influence	12	2,51
Positively	369	77,20
Very positively	76	15,90

Category: Didactics - Subcategory: Form of assessment tests

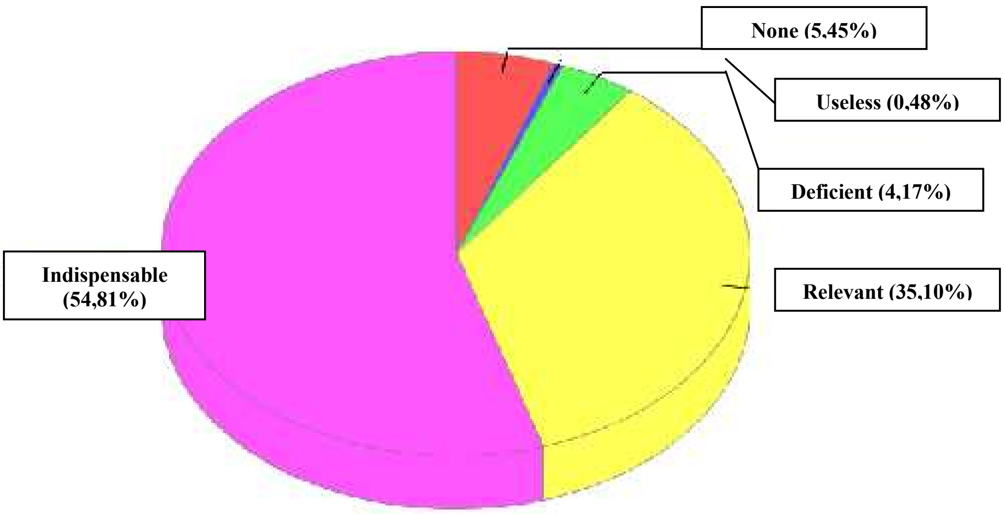
Option	Σ	% Σ
None	53	11,09
Very negatively	3	0,63
Negatively	20	4,18
Without influence	50	10,46
Positively	309	64,64
Very positively	43	9,00

Category: Didactics - Subcategory: Subsunsors

Option	Σ	% Σ
None	46	9,62
Very negatively	1	0,21
Negatively	17	3,56
Without influence	23	4,81
Positively	305	63,81
Very positively	86	17,99

As factors related to their professionalism, teachers rate the usefulness of their training contributions (60.88%) and rate very positively the domain of disciplinary content (98.28%).

On the other hand, teachers give importance (86.82%) to the factor *"interaction with colleagues"* when teaching science. The following chart shows:



With regard to teachers´ opinion on actions to improve science education (Question 8), they strongly recognize the importance of increasing physical and financial resources (78.03%) and construct special laboratories (69.04%). Thirdly, they ask for secure connections to Internet (55.65%).

Regarding policies to reorient the teaching of science they believe in a percentage lower than 50% in the importance of changing training processes (initial and continuous), reorganizing the work of teaching and engaging extra-school staff (assistants, bilingual teachers) in educational practice. In terms of public policy a 63.39% think that it should be changed the criteria for teacher selection.

Category: Professional - Subcategory: Exchange with colleagues on successful or not experiences in the classroom

Option	Σ	% Σ
None	21	4,39
Useless	3	0,63
Deficient	22	4,60
Relevant	170	35,56
Indispensable	262	54,81

Category: Professional - Subcategory: Link teaching practice/educational research

Option	Σ	% Σ
None	39	8,16
Useless	7	1,46
Deficient	11	2,30
Relevant	195	40,79
Indispensable	226	47,28

Category: Didactics - Subcategory: Devolpmentent of new didactical materials

Option	Σ	% Σ
None	23	4,81
Useless	7	1,46
Deficient	8	1,67
Relevant	150	31,38
Indispensable	290	60,67

Among the professional factors teachers highlight the importance of sharing with colleagues and of linking their practice with the results of educational research (88.07%).

The study also reveals the need of new materials developing, recognized by 92.05%, and achieving mastery of disciplinary content (98.28%), giving support to a better science teaching.

CONCLUSIONS

478 elementary school teachers answered a 14-items questionnaire. Questions arise opinions and conceptions about the basis of science teaching: the influence of didactical approaches and of professional background as well as cultural issues, such as socio-cultural and interpersonal relations factors which improve or impede a better science teaching. This survey has TRACES research project as a framework.

Question 6 and 8 are selected because they refer to the inner classroom practice of teachers by considering the practice itself or the pre-service teacher´s training or the in-service teacher training, the interaction with colleagues, as well as the importance given to the didactical devices.

It is stressed the importance of ensuring teaching science through content mastery and teaching strategies management. It is remarked the importance of providing didactical materials and financial resources, laboratories, internet connections when teaching sciences. Teachers also give importance to guidelines and evaluation criteria and presence of learning subsunsors. As professionals they recognize the convenience of working with colleagues and the contribution of researchers to their professional practice.

These results, from a didactical or a professional point of view, allow the design of successive research phases looking for narrowing the research-practice gap, the principal TRACES objective.

ACKNOWLEDGEMENTS

Authors express their acknowledgement to all the members of the Salta TRACES Group for their commitment and efficiency in the survey instrument´s adaptation and application in the Province of Salta. We are particularly grateful to Prof. Mónica E. Moya for her collaboration in the data analysis.

INTEGRATED TEACHING OF SCIENCE AND TECHNOLOGY IN FRANCE: AN EXAMPLE OF A COOPERATIVE TEACHING.

Maryline Coquide[1], *Corinne Fortin*[2], *Christophe Lasson*[3]
[1,2,3]STEF ENS Cachan / IFe ENS Lyon

Abstract: In France, since 2006, an Integrated Teaching of Science and Technology (ITST) has been set up as innovation in middle school. First and foremost its goal is to bring a new unit of teaching in which Science and Technology are not poles apart from different disciplines. The implementation of ITST by teachers usually specialized in one discipline (biology, physics or technology) needs to develop news teaching ways. Within a theorical framework Didactic of Curriculum and using a methodology based on Content Pedagogical Knowledge (PCK), are mobilized by teachers to implement ITST. This data was collected from two sources : official instructions and video recordings teachers' meeting to prepare lessons or teaching in classroom. The results show the emergence of a new curriculum, and a new approach of teaching but without necessarily devoting oneself to one skill widening from initial discipline teaching.

Keywords : curriculum- cooperation – specialist – integrated – school discipline

1. INTRODUCTION

Integrated Teaching Science and Technology (ITST) is promoted to prospect for European and International Education Program. Instance of this, Quebec in 2007 gave up the former scheme in distinct disciplines, so that integrated teaching could be kept on. Australia, Taiwan, Greece have also experimented an integrated teaching. In France, the French Ministry of Education and the National Academy of sciences and technology has been supported ITST as an innovation since 2006. To implement ITST, Inquiry-based Science Education (IBSE) is recommended and two main topics are concerned that is : Energy and Material. Actually, fifty middle schools have taken part in ITST innovation, including pupils for grade 6 (age 12).
In France, ITST contrast with the traditional scientific teaching. Usually biology, physics and technology are three main disciplines taught in secondary school. As regards ITST, a teacher specialized in one of these disciplines become a teacher of Science and Technology (Fig 1).
ITST is a new teaching and a new professional experience for teachers. To keep up with it, the latter must share their conceptions about integrated teaching and build on a new way of teaching. Drake (2007) explains how teachers must overcome their resistance to elaborate integrated approaches and strategies. They need to cross different approaches (multidisciplinary, interdisciplinary, or transdisciplinary) and different teaching strategies to include thematic subjects, learning projects, IBSE practice in integrated curriculum.

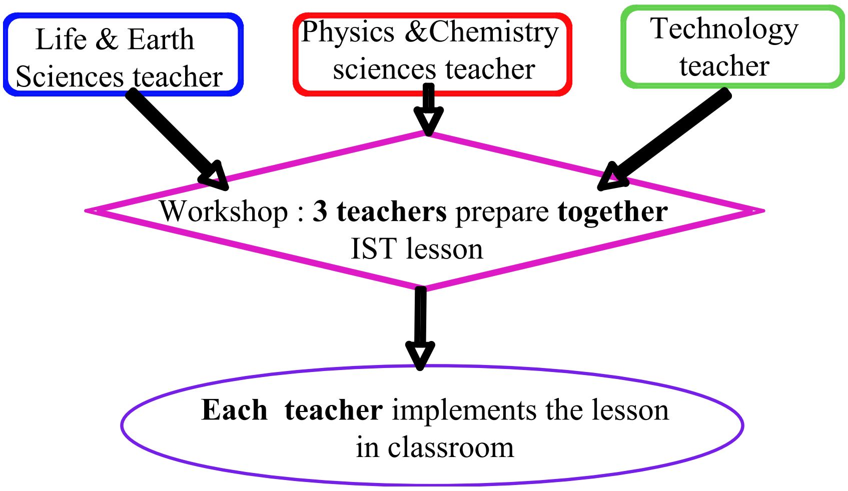

Fig 1. Organization of ITST

This new teaching device have a significant impact on teaching practice and relationship between teachers. For example, to get ready to work out a lesson, three specialized teachers, each one in one discipline, meet once a week to carry out choices and make decision. But, implementation of ISTS is conducted by each teacher in classroom of S& T.

2. RATIONALE

Firstly to study the collective construct and the individual practice, we are likely to use the framework proposed by Martinand (2003) going through curricular steps. By curriculum, we are acknowledged upon official instructions, not to mention the references that guide teachers' choices. Our analysis is based on four steps (Fig 2).

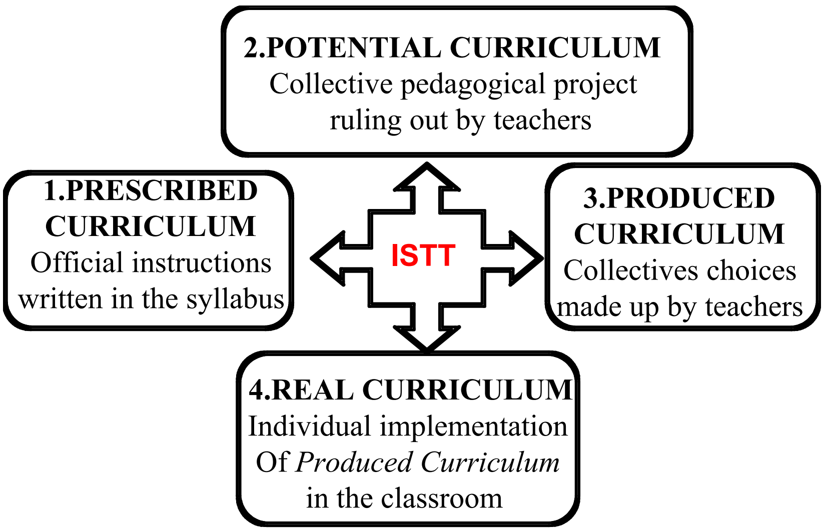

Fig 2. Stages of curriculum development

- *Prescribed curriculum*, i.e. official scientific or technological content for each discipline and also pedagogical activities for pupils;

- *Potential curriculum* is characterized by different teachers's interpretations of the prescribed curriculum;
- *Produced curriculum* is a transcription of the teachers's choices within different interpretations from the prescribed curriculum ;
- *Real curriculum* corresponds to what each teacher really implements in his classroom.
As for each curriculum, the purpose is to identify which knowledge is mobilized by teachers and what difficulties they encounter in implementing ITST.
Our hypothesis is implementation of ITST requires for specialized teachers (biology, physics or technology) to go well beyond the field of their own disciplinary teaching and eventually acquire new professional knowledge. How does a specialized teacher became involved in ITST and jointly worked out the ISTT implement ?

More precisely, we question :
- The relationship between specialized teachers to implement ITST;
- The stand of the teacher either a teacher of « S&T » or a specialized teacher who will bring out his expertise in ITST;
-The role of the IBSE to unify S&T;
- The meaning of the "I" of ITST does it mean integration of disicpline, interdisciplinary, unlikeness of school disicpline ?

Thus ISTT implementation requires :
- firstly to cross school disciplines
- secondly to acquire a new professional expertise connected with a new way of teaching.

The goal is to determine what pedagogical knowledge are summoned up by 3 teachers to develop and implement ISTT.

3. METHOD

We hold on a case study two teams (from two different middle schools) of three teachers, each one specialized in biology, physics or technology.

Data collection and corpus

Data collection is provided
- for the *prescribed curriculum,* content of official instructions in ITST and also supplied by two curricula topics namely "Energy" an "Material";
- for the *potential curriculum,* with exchanges and negotiations talk between the three teachers to get ready the lessons in ITST, from transcribed video recordings (10 hours);
- for the *produced curriculum*, with the notebook where team-teachers write down the choices of progression, demonstrations, explanations to help the learners.
- for *the real curriculum*, with the interventions of each of the three teachers in ITST classroom, from transcribed video recordings (10 hours).

Analysis of the corpus

To answer our research questions, we try to determine what knowledge is mobilized by teachers according to four curricula above. Analysis of the corpus has been based on *Pedagogical Content of Knowledge* (Shulman, 1987) :
- *Subject Matter Knowledge (SMK)* or content knowledge in academic disciplines,

- *Pedagogical Knowledge (PCK)* or teaching knowledge to transform the content ITST into a powerful pedagogic (illustrations, demonstrations, explanations...),
- *Knowledge of learners (KL)* or misconceptions, taken into account of the learning difficulties to the pupils,
- *Curricula Knowledge (CK)* or content knowledge of the school curricula and the pedagogical equipment available (laboratory material, software...) to implement ITST.

For example during the concertation meeting to elaborate the *potential curriculum*, teachers refere to Energy concept. At first, starting from their own discipline, each of them gives a specific definition, and so, they mobilize SMK from academic disicpline. After that, the discussion is concerned with what kinf of examples are likely to be choosen to illustrate energy. Teachers of technology and physics propose electric energy while the teacher of biology will propose muscular energy. In this case, each teacher mobilizes “disciplinary PCK”. But sometimes, team-teachers try to combine transversal examples of energy as a common transformation process from a source (sunlight for electric energy or nutriments for muscular activity). In this case, they mobilize a shape of “integrated PCK”.

4. RESULTS

The analysis highlights different results.

- As for the *prescribed curriculum*: Content Knowledge of biology and physics and technology are patchwork-stuck. Moreover, a tension between disciplinary curricula and the interdisciplinary topics in ITST results in.
Out of 34 items in the Teacher’s Guide book « Matter and Materials » the graph (Fig 3) shows the distribution between school disciplines. We note down that traditional school disciplines are a minority compared to cross-disciplines.

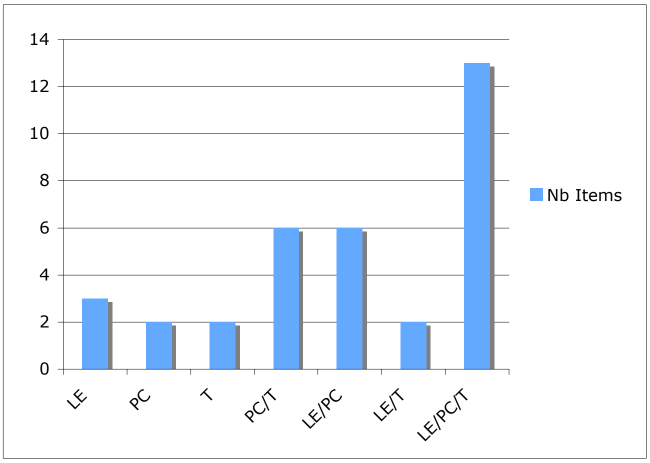

Fig 3 : Distribution items according to school disciplines in the guide book
(LE : Life and Earth science, PC : Physic and Chemistry science, T : Technology)

Each school disciplines items mobilize MSK (e.g concepts : matter, energy, cell, technical object …) and then, when one crosses disciplines items, PK is mobilized.

- As for the *potential curriculum*: collaboration and cooperation between teachers is vividly expected about content knowledge in academic disciplines, about teaching Knowledge to clear up the pedagogical goals for ITST and decide the many choices to get through with it.

During the discussion between the three teachers, four types of knowledge are mobilized :
- MSK are summoned to try a common definition of energy
- KL to anticipate the difficulties to be overcome and pupils'skills to undertake something…
- PK to plan the lesson.
- CK about laboratory equipment useful for the lesson

The graph (Fig 4) shows that a great deal of time is spent upon the discussing of laboratory equipment and planning lesson (e.g some teachers do not know how to use the laboratory materials : a miscrocope, a drill, a software, or else and so, they need to be guided with a specialist teacher's eye).

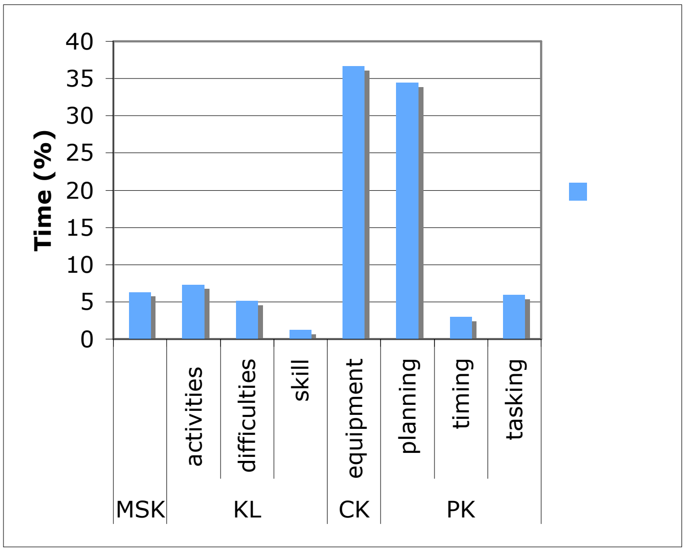

Fig 4. Units of discussion and time spent (%) during a working meeting (92 min)

- As for the *produced curriculum*: plan, organization and activity tasks for learners (Fig 5).

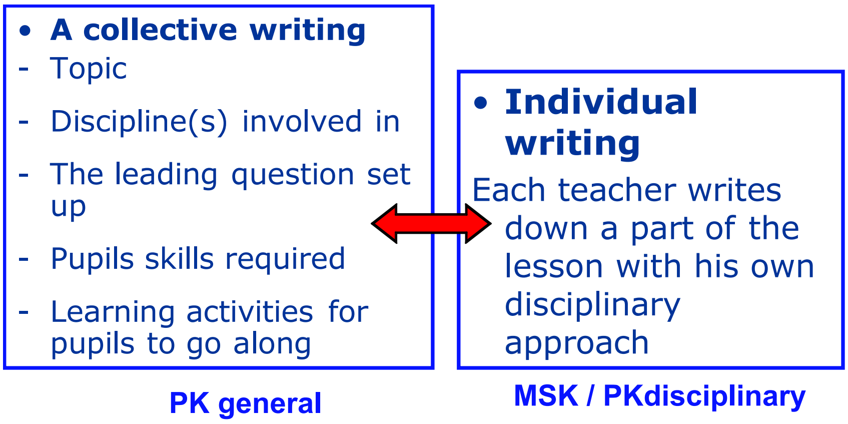

Fig 5. Organization of the working paper for the lesson

On the one hand, PK about the plan of a lesson are summoned up by a teacher team to produce a working paper, in 5 points come to focus : topic/ discipline involved in /, the leading question set up/, pupils'skills required and learning activities for pupils .

On the other hand, each teacher writes down a part of the lesson with his own disciplinary approach (MSK or PK disciplinary).

Concerning the tasks appointed to the learners about specific concept (i.e construct a breeding cycle), team teacher delegates the drafti of the learning task to the teacher who is recognized by all, as a specialist (in this case the teacher of Biology is called in). That is, each teacher bring its expert testimony in a discipline to an integrated teaching. So to say, each team of teachers form each school produces a "local" curriculum, that is to say, they don't exactly choose the same pedagogical goals or activities tasks for learners.

- As for the *real curriculum*, each teacher introduces him(her)self in classroom of « S&T » as a teacher of S&T and not as a teacher in biology, physic nor technology Nevertheless, teachers don't always master the MSK the learners are due to be taught. Teachers can't figure out the difficulties or the misconceptions of learners and sometimes are unable to answer their questions. This deficiency is compensated with a friendly talk between teachers. In this case, the teacher explicitly tells the pupils off that he must seek out for a specialist teacher's help to fill in the gap of the expertise knowledge of the disciplines. He or she mobilize cooperation knowledge.
To describe IBSE, each teacher does reference to the professional practices from academic discipline. Thus, two ways of thinking IBSE arouse either experimental method with scientific practices for teachers in biology and physics, or design method with manufacturing practices for teachers in technology.

5. CONCLUSION

In comparison with other studies, in particular the Australian study led by Wallace & al (2007) we have also noted a disparity between Integrated Curriculum prescribed and the real practice in ITST, because Integrated Curriculum practice doesn't exist. ITST is a new way of teaching without professional memory assess or pedagogical tradition. If group work is recommended, the organization is very disparate according to the schools.

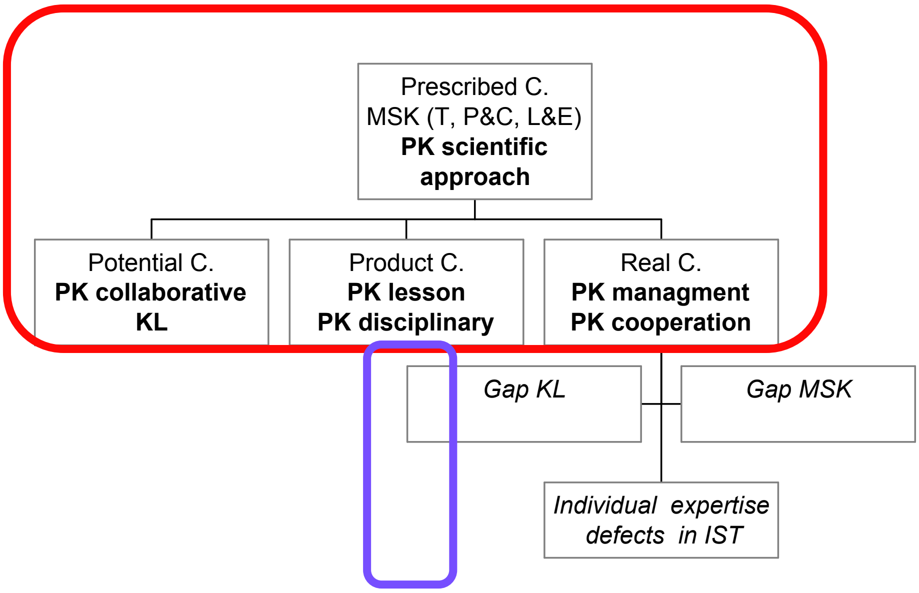

Fig 6. Knowledge mobilized in the developement of local curriculum
(Red frame : collaboration and cooperation between the 3 teachers, blue frame : limit of professional enlargement in S&T for each specialized teacher)

In conclusion, each curriculum is characterized by different knowledge and it is difficult for each specialist teacher to go out of the speciality field.
The implementation of ITST in classroom, from a local curriculum collectively produced needs worthwhile collaboration and cooperation between specialist teachers. Still, it appears that there is no professional widening from the speciality.
Anyhow, the collaboration seems to open prospects with new disicplinary interactions. Noting collaboration between teachers from different disciplines constitute here a real newness in the professional development. Meanwhile, there is a paradox. At the moment, ITST innovation in France is more a juxtaposition of disciplines rather than a real integration. But, it also appears that the meaning of "integration" in ITST must be understood like the disappearance of the school disciplines in a new school discipline « S&T ». At all events, this new integrated teaching seems to raise a new speciality teaching claim for an ITST specific curriculum.

SEMIOTIC MEDIATION AND DIDACTICAL CYCLE AS METHODOLOGICAL REFERENCE FOR PRIMARY SCHOL TEACHERS

Federico Corni[1], Enrico Giliberti[1] and Cristina Mariani[1]

[1]Department of Education and Humanities, University of Modena and Reggio Emilia, Viale A. Allegri 9, 42121 Reggio Emilia (Italy)

Abstract: The theoretical framework of semiotic mediation, after a Vygotskian approach within activity theory, fruitfully introduced for mathematics education, has been transposed and adapted to laboratory science education activities. Aim of this paper is to show how this framework can be used as a methodological reference for teachers to mediate scientific meanings. An example addressed to teachers of application to laboratory activities with a jet car toy is proposed.

Keywords: Semiotic mediation, Force Dynamic Gestalts, Energy, Didactical cycle, Primary school science education

DEFINITION OF THE PROBLEM

Primary school teachers have difficulties in teaching sciences and in particular in driving laboratory activities, addressed to meaning construction and modeling, to achieve a lasting effect of science education. Science laboratory activities risk to be reduced to a set of trivial practices, or mere manipulation, or twiddling, to be executed by students, without the suitable and precise teacher's guidance, while, according to the Vygotskian perspective of *obucenie* (Mecacci, 1990), the teacher's active role is fundamental. In literature or in textbooks, a wide variety of educational school courses is documented, while effective methods on teaching /learning processes are not so widely available. In this contribution, after a synthetic presentation of a proposal of a methodological framework, an example of semiotic approach to introduce students' to energy meaning construction will be presented and discussed.

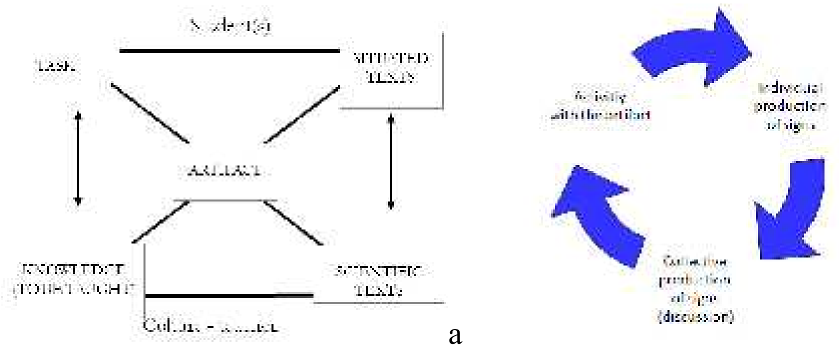
PLACE IN THE LITERATURE

In mathematics laboratory education exists a well defined and consolidated framework of semiotic mediation (Bartolini & Mariotti, 2008) to guide and foster methodological and educational competencies in teachers. This fits Vygotskian tradition that considers learning a mediated relation between individuals and knowledge. Artifacts and instruments are key terms of Rabardel's theoretical construct that defines an instrument as "a mixed entity made up of both artifact-type components and schematic components that we call *utilization schemes*. This mixed entity is born of both the subject and the object. It is this entity which constitutes the instrument which has a functional value for the subject" (Rabardel & Samurçay, 2001). However Rabardel's approach is not enough to be used in teaching/learning processes in which

Vygotsky's analysis of technical (artifacts) and psychological (sign)[1] tools and Hasan's (2002) investigation of complex semantic relations of mediation processes are necessary. In the learning process, a child needs the help of the teacher to cross the Vygotskian zone of proximal development and to internalize new knowledge.

SEMIOTIC MEDIATION AND DIDACTICAL CYCLE FOR SCIENCE

The key terms of Bartolini & Mariotti's framework can be reinterpreted to suite the specific case of science. Fig. 1a reports the sketch of the elements and the links of the theoretical framework of semiotic mediation adapted for science.



a b

Fig. 1. Elements and links of the (a) theoretical framework of semiotic mediation and (b) the didactical cycle

At the centre of the laboratory work there is an *artifact*. The artifact, may be any scientific "instrument" available in scientific laboratories (easily assimilated to mathematics artifacts and to Rabardel's genèse instrumentale) or the reproduction in the laboratory of a piece of reality, according to the analysis of Knorr-Cetina (1999), with the aim of simplifying and focusing particular aspects. The artifact embodies meanings that students have to discover and internalize, and this is stimulated by the *task*. The task, a question or a problem posed by the teacher, reflects the fundamental steps of a scientific research. The tasks may refer, for example, to the description of the artifact itself and of the function of its parts, or to the prediction of its behavior under certain conditions, the solution of a problematic situation or the way to achieve a certain result, the description of a process or of a phenomenon involving the artifact, its interpretation, the identification of relevant invariables as well as their relations. The teaching-learning process starts with the emergence of students' personal meanings in relation to the use of the *artefact* The students, stimulated by the task, construct personal meanings through *utilization schemes* of the artifact, i.e. from simple manipulation and exploration of the artifact, to well designed experiments with choice of the parameters and of the quantities to be varied and measured. The teacher's role here is again fundamental and well defined. By all these activities children produce some specific personal *signs* (written or oral words, gestures, drawings,...) that the teacher may recognize and interpret as "pivot" signs to be made evolving. "pivot" signs may be used by the teacher to create a link between the plane of concrete experience and the plane of meanings, for the evolution towards *scientific text* and the processes of meaning construction. Their evolution has to be fostered by the teacher through specific social activities. In summary, the process of semiotic mediation consists in the evolution process that has its first step in the emergence of personal meanings related to the accomplishment of a task and develops in the collective construction of shared signs related to both

[1] The sign acts as an instrument of psychological activity in a manner analogous to the role of a tool in practical activity

the use of the *artifact* and the science to be learnt. This evolution is promoted through an iterate cycle (Fig. 1b) that includes (i) activity with the artifact, (ii) individual production of signs, and (iii) collective discussion, pointing at the shift between the *situated texts* produced by the children (Fig. 1a) to forms of *scientific texts* (suitable to students' age) that are decontextualized from the specific situation and, at the same time, able to evoke the concrete experience. Each of these activities contributes differently but complementarily to develop the complex process of semiotic mediation (Bartolini Bussi & Mariotti, 2008). *Activities with the artifact* constitute the start of the cycle. They are based on tasks, as are designed with the aim of promoting the emergence of signs related to artifact use. In some activities students are involved *individually*. For instance, students might be asked in classroom or as homework to write individual reports on the previous activity with the artifact, reflecting on their own experience and raising possible doubts or questions, to find analogous situations to the studied one. Written productions can become objects of discussion in the following *collective classroom discussion*. This third activity plays an essential part in the teaching-learning process and constitute the core of the semiotic process, on which teaching-learning is based. The whole class may be engaged: for instance, after a laboratory activity, the various individual or small group descriptions and interpretations (students' written texts or other texts) may be analysed, commented and discussed collectively. The main objective of teacher's action in such a discussion is that of fostering the move towards science meanings, taking into account individual contributions and exploiting the semiotic potential coming from the artifact use (for the elaboration of the concept of Mathematical Discussion, see Bartolini Bussi, 1998a, 1998b).

In the different steps of the methodological framework we have here illustrated the teacher's role is different and crucial. It ranges from the choice of suitable tasks, which exploit the semiotic potential of an *artifact*; to the professional recourse to suitable interaction strategies during the tricky step of classroom discussion. The study of the teacher's role is in progress in pilot experimentations with teachers-researchers and in the diffusion of classroom activities with *artifacts* to the broad education system.

A POSSIBLE TEACHER TRAINING PATH ABOUT ENERGY

In order to apply this methodology, teachers need first to be trained, putting themselves in the same situations (i.e. using the same artifact, answering to similar tasks, producing and discussing pivot signs they expect from students) they could offer to their students, thus to experience possible difficulties and needs of children and to focus science knowledge in relation to children experience urged by the artifact use as *instrument.* In the following, we outline an example of contents of an application of the semiotic mediation framework addressed to teachers with children of the 4th and 5th grades. We will refer to the elements shown in Fig. 1.

The piece of knowledge to be taught. The concept of energy is very hard to be understood by young students. However some basic concepts can be introduced very early to prepare the scientific meaning construction in a vertical curriculum perspective, i.e. the identification and differentiation, teacher guided, of the Force-Dynamic Gestalts (FDG) (Fuchs, 2007). They are the schemas that the mind uses to make sense of experience, by metaphorically projecting them onto concrete phenomena. Various phenomena, such as those involving the behavior of fluids, electricity, heat, motion, and chemicals, treated separately by different fields of science, can be understood in terms of analogous basic and simple structures already present in children's minds (Fuchs & al., 2011).

Metaphoric actors of natural processes are fluid-like quantities (extensive quantities), with associated intensities (generalized potentials or intensive quantities) which differences (potential differences) drive fluxes. The power of a process in an interaction is determined by its quantity and the connected potential difference: a certain increase of potential of a certain quantity (effect of the interaction) occurs at the expense of a certain decrease of potential of another certain quantity (cause in the interaction). The concept of energy then arises from the identification of the "proportion" between two processes taking part in an interaction.

The artifact. We consider a jet-car toy (Fig. 2).

Fig. 2: The jet-car artifact.

Other artifacts can be, for example, a putt-putt boat, a windmill, a dynamo torch, or, with reference to natural sciences, a tree, an ecosystem, the blood circulation, the water cycle, chemical reactions etc.

The task. The tasks invites observing and investigating how a device (a toy) functions; the relationships between its parts; how the problematic situations posed by the task may be solved; the prediction of the behavior of the apparatus under certain initial conditions; the interpretation of the observations (Mariani & al., 2011). With reference to the jet-car, the tasks can be grouped as: (A) exploration of the toy as an artifact (Describe the jet-car. Describe and draw by which parts is it composed); (B) exploration of the experimental apparatus as a tool (How could you use it? How could you make the car go faster? Or go further?); (C) use of the toy with utilization schemes (After the experiments: What did you do with the jet-car? What did the car do? How do you explain your observation? Perform several experiments with the inflated balloon to move the toy car by changing the air in the balloon and the mass of the car. Make changes one at a time); (D) search for relationships, detailed analysis of the toy (balloon inflated and exhaust hole kept closed: What quality has the air in the balloon? What does the air "feel"? What quality has the jet-car?; exhaust hole open: What quality has the air while it is coming out of the hole? What does it "feel"? What quality has the air after it is come out of the hole? What does it "feel"? What quality has the jet-car while the air is coming out from the hole? What does it "feel"? What quality has the jet-car after all the air has come out of the hole? What does it "feel"?). Each task generates a didactical cycle.

The evolution of situated texts towards scientific texts. In a real case, for every task, children produce sentences, words, expressions, drawings, sounds, gestures that the teacher may recognize as "pivot" signs. For example, during a collective discussion, pivot signs could be: "air is trapped", "a wind exits the hole", "air mixes with outer air", "the car moves forwards while the air is blown out", "the car gradually stops", "more air-more speed", "all is resting",… Teachers, once invited to hypnotize possible students' situated texts, have to be trained to conduct collective discussions for gradual construction of scientific meanings starting from the pivot-signs. The steps in the case of energy could be: i) description of the process as a whole using common language; ii) refinement of the language used, stressing quantities that play a role; iii) description of the process in terms of fluid-like quantities, associated differences of potential and elementary concepts (current, resistance, capacitance, etc.); iv) interpretation in terms of cause-effect (so far the word "energy" is still not used); v) introduction of energy as proportion between causes and effects.

A possible scientific text that teachers should make is the following. *When the balloon deflates, the car accelerates, reaches maximum speed and gradually goes to rest. The air expelled backward pushes the car forward. The car moves but, at the same time, loses motion. After the balloon is completely deflated, the car looses all its remaining motion and stops.* A more formal text could be the following. *The air expands due to the pressure difference and exits at high speed from the car nozzle. Thus momentum is transferred to the car proceeding in the opposite direction. The car accumulates momentum and, at the same time, transfers part of it to the earth as a consequence of the velocity difference. When all air has been expelled, the car momentum gradually flows to the earth until the velocity difference becomes zero. The air pressure causes the transfer of momentum from the air to the car, air interacts with the atmosphere and car interacts with earth causing production of heat. The energy contained in the compressed air is transferred to momentum (a greater fraction to the air than to the car) and from momentum to heat.*

CONCLUSIONS

We have proposed a methodological framework of semiotic mediation and the didactical cycle worth introducing to teachers as reference for scientific meanings construction in laboratory activities.

The various elements and links have been discussed and exemplified for the case of energy meaning construction. This work shows the feasibility to anchor scientific meaning construction to children's reasoning, starting from the image schemas of the FDG, suggesting a methodology that makes the teacher confident in the use of natural language.

SCIENCE TEACHERS' NARRATIVES ON MOTIVATION AND COMMITMENT – A STORY ABOUT RECRUITMENT AND RETENTION

Peer S. Daugbjerg[1]
[1]Ph D Student, Department for Learning and Philosophy, Aalborg University and Senior Lecturer, VIA University College, (pd@viauc.dk)

Abstract: Evidence of problems in science teacher recruitment and retention are often provided in statistical overviews. The individual science teacher's recruitment is based on subjective motivation, and retention is based on continued motivation and commitment to science teaching. Narratives constitute a way to learn more about the individual teacher's motivation and commitment. Narratives were collected from 10 Danish science teachers, teaching 4th to 10th year science subjects. This paper focuses on two of these. Their motivation for choosing and staying in science teaching differs. Tina was recruited into science teaching through inspiring teachers in primary and high school and a desire to do good for others; this motivated her to choose teacher education and biology as a major teaching subject. After 9 years of teaching she is retained in teaching by her commitment to treating the children as whole human beings. Jane was recruited into science teaching by an interest in outdoor life; this motivated her to choose teacher education and biology as a major teaching subject. After 32 years of teaching she is retained in teaching by a commitment to developing outdoor science education. Teachers' narratives give individual stories of science teacher student recruitment, as well as retention for in-service science teachers. It is the individual choices of coming and active science teachers that sum up in the recruitment and retention statistics.

Keywords: Narratives, Commitment, Motivation, Retention, Recruitment

BACKGROUND

Teacher recruitment and retention has been an area of much interest (e.g. Cooper & Alvarado, 2006; Guarino, Santibanez & Daley 2006; Nordisk Ministerråd, 2009; Hare & Heap, 2001). In many countries there are reports on problems of imminent shortages of science teachers (Danmarks Lærerforening, 2007; National Comprehensive Center for Teacher Quality, 2007). The above studies provide mostly statistical overviews of the problem, which show the magnitude of the present problem and the expected development of the future problem. In Denmark e.g. only 57% of the lower secondary teachers teaching biology have completed subject matter education in biology and only 18% of the teachers teaching primary science have completed subject matter training in primary science (Danmarks Lærerforening, 2007). Such statistics gives an idea of the scope of the problem, but do not provide any insight in the individual teacher's reasons for and approach to teaching science.

Many studies focus on the first difficult years of teachers' professional careers studying different forms of mentor programmes and their effect on the retention of newly started teachers (Ingersoll & Smith, 2004; Hanuscin & Lee, 2008 and Luft, Wong and Semken, 2011). Luft, Wong and Semken (2011) call for a more comprehensive and strategic orientation towards the recruitment of secondary science teachers, and they recommend more focus on the induction period and science teachers' start of their professional career. Such studies on induction programmes are beneficial for expanding our understanding on relations

between recruitment into and the start of science teacher careers, but do not provide insight into the long-term retention over an entire science teacher career.
Recruitment and retention studies on teachers use different approaches such as questionnaires among first year teacher students in order to understand the social and cultural background for recruitment to teacher education (Stage Petersen, 2010); or narrative inquiry in order to understand details in teachers' life and work contexts (Day et al, 2007). This paper will present experienced science teachers' narratives on their experiences in the teaching profession. The research interest is focused on understanding long-term retention through questions on the reasons why the individual teacher chose a teaching career and why the individual teacher chose science as a teaching subject.

RATIONALE

Science teachers' narratives on their choice of education and on their practice is a way to learn more about the recruitment into science teaching as a profession, and the retention in it over an entire career. Persson (2009) interviews teacher students in Sweden and find their recruitment being motivated by experiences prior to starting on teacher education. Using their narratives he is able to describe their subjective motivation for choosing teacher education and to partly understand the underlying social recruitment patterns. He distinguishes between 4 types of motivation: walk in the footsteps of a master, work with your hobby, invest in teacher education, and avoid beers and mopeds.
Day et al (2007) has made an extensive study of teachers' lives, work and effectiveness in the UK using both qualitative and quantitative methods. They distinguish (ibid, p. 213) between two types of retention: a physical continuation, and a maintained commitment and motivation. They base the latter retention type on interview-generated teacher stories and conclude that commitment has major implications for teacher effectiveness.
This paper will discuss these types of motivation and retention using narratives on initial motivation and the commitment of two science teachers in Denmark. The science teacher narratives on motivation and commitment illustrate aspects of recruitment into and retention in science teaching.

METHODS

The narratives were collected in the autumn of 2010 and the spring of 2011 during an ongoing Ph. D. research project in Denmark. The project uses primary and lower secondary school science teachers' life histories to investigate their motivation for and commitment to science teaching. The research design is inspired by Norrie and Goodson (2011) using life-history interviews, observation of the teachers teaching, and collection of materials produced by the teachers such as pupil assignment sheets, subject-oriented letters to parents, and written in-service training assignments, etc. The narratives will be presented in a condensed form in this paper; all translation is done by the author.
The teachers were chosen so that they have several years of teaching experience; such teachers are past the first troublesome years in a teacher career. Their long experience in science teaching makes it possible for them to tell about the long-term retention in focus in this research project.

RESULTS

The 10 teacher-narrators represent 6 schools placed in different socio-economic settings. The teachers have all completed the 4-year teacher education in Denmark; they have attended 3 different colleges of education for their pre-service qualification. They are all qualified for teaching in Danish public education from 1st to 10th year. Table 1 presents background data of the teacher-narrators' life and education prior to their teaching practice. The two oldest teachers were recruited directly from high school, whereas the others all had other work or educational experience prior to starting their teacher education. This pattern of delayed recruitment including changes from other careers into teaching has become more frequent during the last decades in Denmark (Stage Petersen, 2010).

Teacher alias	Gender	Year of Birth	High school or similar finished in	Other training or employment prior to teacher training	Start of teacher education	Graduation as teacher
Jane	♀	1954	1974		1974	1978
Erik	♂	1957	1977		1977	1981
Lars	♂	1956	1976	Clerk	1982	1986
Diana	♀	1970	1990	Shop assistent	1992	1996
Linda	♀	1956	1994	China Painter, shop owner	1994	1998
Simon	♂	1971	1990	Laboratory worker	1997	2001
Tina	♀	1975	1995	Kitchen assistent, Videoshop manager	1997	2001
Frank	♂	1973	1997	Farmer, Nursery assistent	1999	2004
Karen	♀	1966	1985	Industrial worker	2001	2005
Ruth	♀	1972	1992	Nursery assistent, Occupational therapist	2002	2009

Table 1: Background data of the 10 teacher-narrators.

The two teachers in focus, Jane and Tina, were chosen since they represent different commitment to and motivation for science teaching. Jane teaches 4th to 6th year at a school with 400 all Danish-speaking pupils in a small town of 8,000 inhabitants. She is married to a farmer and lives on a farm; she was born in a town 30 km from her present home. Tina teaches 7th to 10th year at a school in a town of 25,000 inhabitants. The school has 800 pupils of whom 200 are bilingual. She is married to a mechanic and lives in the town where she was born and now teaches. Jane and Tina were both trained at a teacher college (approx. 125 teacher students at each year) close to where Jane now lives. In pre-service education Jane was educated in Biology and Sports as her major teaching subjects, whereas Tina was educated in Biology and Danish.

Motivation for choosing science teaching

The majority of the 10 teacher-narrators tell that they chose teaching because they care for children and other people. Tina is in accordance with this majority in describing her motivation for choosing teacher education.

> Tina: From 1st to 6th year I had a male class teacher, he was so nice, a very good newly educated male teacher. What he gave us I also wanted to give someone someday.

Jane has another motivation for choosing teacher education; she considered university studies in biology or a career as ballet dancer.

Jane: After high school I wanted to be either a ballet dancer or game biologist, in teacher education I could get a bit of both. The teacher college wasn't that far away, I had a sick mother at that time.

All the teacher-narrators have positive experiences with science education, nature preservation or outdoor life prior to entering teacher training. Jane and Tina illustrate different types of experience that have motivated them to choose biology as a major teaching subject.

Jane: I loved helping out at my uncle's farm. Our holidays were fishing trips. It was obvious for me to choose biology as a subject for teaching, biology has been THE line for me.

Tina: I had the nerdiest nerd in biology in high school, but he was very funny, he had a good approach to biology ... very good at making images in our heads.

Jane's narratives are in accordance with Persson's 'work with my hobby' type of motivation, and she is still very active hunting and caring for game in her spare time. Tina's narratives are an example of Persson's 'walk in the footsteps of a master', she tells of no science or nature related hobbies. The narratives presented are more focused on everyday teaching and less oriented towards conditions of employment than discussed in the literature available in general (e.g. Hare & Heap, 2001; National Comprehensive Center for Teacher Quality, 2007)

Commitment to science teaching

The teacher-narrators have very different reasons for still being committed to science teaching. Jane is committed to improving the possibilities for outdoor oriented science teaching as she has raised money to restore a pond near her school, so that it can be used in biology teaching.

Jane: This pond is a little diamond, but it needs restoration so as not to become choked. You should be able to fish for water insects in it.

Tina has taken on the task of being a coach to pupils with emotional problems and in her biology teaching she puts emphasis on sex and health education, which is part of the biology curriculum in lower secondary school in Denmark.

Tina: I want to have a positive influence on the young people. My attitude is that it is half subject matter and half social worker, because we are to turn whole humans out in the end. I'm developing a curriculum for the sex education at my school.

Tina's commitment is the relation to the pupils and their well-being both physically and emotionally as whole human beings. Jane and Tina both show continued commitment and motivation to developing science teaching at their schools, which is in accordance with the way Day et al. (2007) describe maintained commitment and motivation. The narratives give more positive and affective reasons for staying in the science teaching profession than those provided in the literature in general (e.g. Guarino et al, 2006; Hare & Heap, 2001).

CONCLUSIONS AND IMPLICATIONS

The teacher-narrators carry their initial motivation for choosing teaching into their science teaching practice. Tina was recruited into science teaching through inspiring teachers in primary and high school and a desire to do good for others; this motivated her to choose teacher education and biology as a major teaching subject. After 9 years of teaching she is retained in teaching by her commitment to treating children as whole human beings. Jane was recruited into science teaching through an interest in outdoor life; this motivated her to choose teacher education and biology as a major teaching subject. After 32 years of teaching she is retained in teaching by a commitment to developing outdoor science education. Despite their commitment to parts of the science curriculum, Jane and Tina teach the entire curriculum of their science subjects with competence.

Teacher education is no longer a frequent first choice of education, which brings different types of experiences of relevance to science into teacher education (table 1). Recruitment to science teacher education could benefit from engaging in initial motivations and prior experiences in order to challenge and develop student teachers' interests and perspectives beyond their immediate motivation for science teaching.

Retention in science teaching can be accomplished through the development of opportunities that support the science teachers' specific commitment. Commitment through participation in on-going changes at their school is typical of all the teacher-narrators as arguments for staying in teaching, not all of these though are related directly to science teaching.

Teachers' narratives give individual stories of science teacher student recruitment, as well as retention for in-service science teachers. It is the sum of individual choices of future and active science teachers that make the recruitment and retention statistics.

REFORM IN BIOLOGY EDUCATION: TEACHERS AND RESEARCHERS IN A PROCESS OF NEGOTIATION

Doris Elster[1]
[1]Institute of Science Education – Department Biology Education
University of Bremen, Germany

Abstract: This study reports the empirical results of the implementation of National Educational Standards in Germany and is part of the transnational European project CROSSNET (Crossing Boundaries in Science Teacher Education). In CROSSNET the term 'boundary crossing' is used as a metaphor for a professional learning process in which participants restructure their knowledge and adopt new routines. This process implies collaboration between communities which differ in their routines and practices. In this study the investigated communities are teachers and researchers who cooperate in the German project 'Biology in Context' (*bik*). *Bik* aims to promote students' competencies in context-based biology education and to support teachers' professional development. Therefore, teachers and researchers work together in Learning Communities (LCs) to transform competency models into practice. The goal of this study is to analyze the processes of boundary crossing in three different *bik* LCs. This analysis is based on Engeström´s activity theory. For the data collection the author uses interviews and protocols of LC meetings as well as instructional materials developed in the LCs. Main outcomes of the study are a better understanding of the elements and the dynamics of this activity system, including the mutual learning process of all participants around context-based and standards-based curricula – the common object of the project.

Keywords: biology education, national standards, learning communities, activity theory, boundary crossing

BACKGROUND AND THEORETICAL FRAME

Facilitating the implementation of National Educational Standards in Germany (KMK, 2004), the project 'Biology in Context' (*bik*) aims at promoting context-based and competency-oriented teaching and learning (Elster, 2009; Elster 2010). To support this goal, *bik* uses a 'symbiotic implementation approach' (Gräsel & Parchmann, 2004): teachers and researchers build Learning Communities (Brown, 1997) to put theoretically-based competence models into practice. Working together, teachers and researchers develop tasks and units, test them in the classes, and reflect on the participants' experiences and the learners' outcomes. In seeking to reform how biology is taught, *bik* puts teachers into a position where they become *'at once the targets and the agents of change'* (Cohen & Ball 1990, p.237).

In this study, the author focuses on the structure and the professional development of teachers and researchers within three independently working *bik* Learning Communities (LCs). The author examines the structure of these three LCs by analyzing teachers and researchers as different 'sub-systems'.

The theoretical frame of this analysis is based on Engeström´s activity theory (Engeström 2001) which is applied to educational research in the following way: It is assumed that a *bik*

LC is an activity system with two interacting sub-systems: the subsystem 'Teacher' and the subsystem 'Researcher' (see Figure 1). These sub-systems are the core unit of the analysis. The teacher or the researcher is the *subject* of the interacting subsystem. The initial *object* could be an idea or an assignment that triggers the collaboration of teachers and researchers. The initial object could be ambiguous, requiring interpretation and conceptualization. It could go through multiple transformations until it stabilizes as a finished *outcome*, e.g. a curriculum product. This transformation is made possible by *mediating artefacts*, both material tools and signs. Within a *bik* LC, the members continuously negotiate their *division of labour*, including the distribution of rewards. The temporal rhythms of work, the uses of resources, and the codes of conduct are continuously constructed and contested in the form of explicit and implicit *rules* (Engeström, 2001).

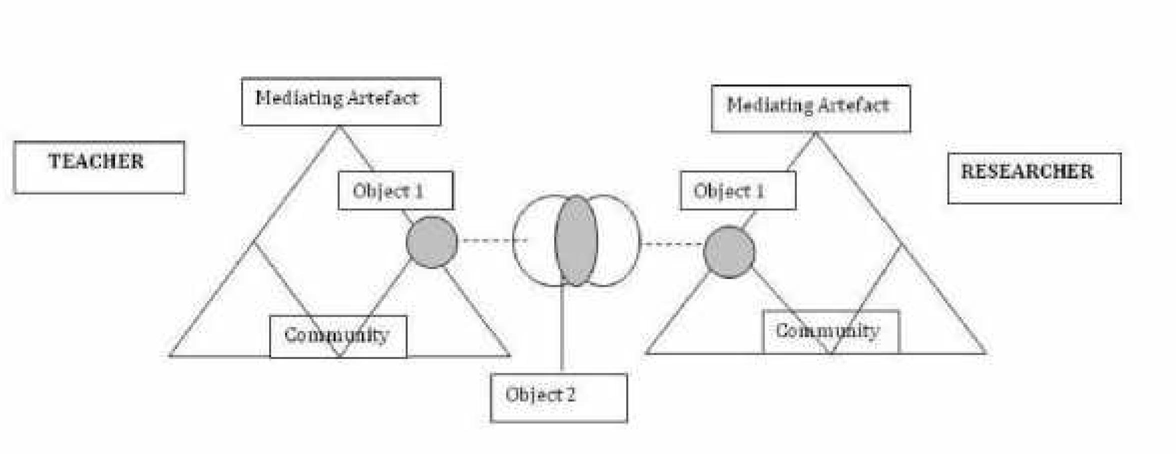

Fig 1: Model of two interacting activity systems ('Teacher' and 'Researcher'), based on Engeström's activity theory (2001, p.131)

Research Questions and Research Design

Based on Engeström's activity theory (Figure 1) the present study addresses the following research questions:

- Interacting acitivity systems: How is the subsystem 'Teacher' characterized? How is the subsystem 'Researcher' characterized?
- What are the boundaries of the participating groups and/or individuals?
- What are the outcomes of the boundary crossing process?

The organizational structure of *bik* involved the construction of Learning Communities (LCs) in the nine participating German federal states. Each LC involved collaboration among 8-16 teachers from different schools types. 144 teachers and 1689 students (aged 10 to 17 years; on average 15 years) participated in *bik*. Each LC was chaired by a coordinator and was scientifically supported by a researcher from the German Universities of Kiel, Duisburg-Essen, Giessen, Göttingen, Münster or Oldenburg. The *bik* project was coordinated by the Leibniz Institute of Science Education at the University of Kiel.

In this study, the structure and the development of *bik* in three different Learning Communities were investigated using qualitative interviews, protocols of LC meetings and analysis of instructional materials developed in the LCs. The interview combined questions about the self-concept as a teacher or as a researcher, the concept of teaching and learning, the 'ideas' regarding the *bik* innovations (concepts, theories, attitudes), the processes, rules, cooperation in the learning community. The interviews were taped and later underwent a qualitative content analysis according to Mayring (2000).

FINDINGS

The findings are structured according to the research questions by (1) analyzing the subsystem 'Teacher' (see table 2) and the subsystem 'Researcher' (see table 3). Then (3) the boundary crossing process f the participating groups and/or individuals are reported. Finally, (4) the outcomes are analyzed.

Analysis of the activity systems

Each *bik* Learning Community (LC) is seen as an activity system that consists of two interacting sub-systems, the 'Teacher' and the 'Researcher'. The individual teacher or the individual researcher is the subject of the subsystem. Pairs of teachers and researchers within an LC are the units of the analysis. These pairs are:

LC1: teacher Kathy and researcher Kim

LC 2: teacher Susan and researcher Sarah

LC 3: teacher Joe and researcher Jane

The common goal within the LCs is the teachers' and researchers' negotiation of competency models and their transfer into practice. Each LC has its own individual starting points and the initial objects (e.g. competency models) differ from each other. It is assumed that the method and strategy of how these initial objects are transformed into final objects (object 2) are different between the LCs. Object 2 can, for example, be a negotiated concept or material to promote students' competences.

Table 2. Analyzing the subsystem 'Teacher'

Sub-system	LC 1	LC 2	LC 3
Teachers	Kathy	Susan	Joe
Similarities	Biology teachers 10 – 20 years of teaching experience		
Community	*Participants:* 7 teachers from different types of school. *Cooperation:* The teachers work in 2-3 small groups on the development of teaching units. They are very critical in the selection of student-relevant contexts. *Rules :* There are no explicit rules that regulate cooperation. Implicit rules are mutual respect, trust, and punctuality. The team's discussions about norms and values are remarkable.	*Participants:* 13 teachers, mainly from High Schools. *Cooperation:* The teachers work mostly in stable pairs. The researcher Sarah presents example units. The teachers test these materials during the LC meetings and later in their classroom. *Rules:* There are no explicit cooperation rules. The teachers behave more like 'consumers' than active developers. They are 'dissatisfied' if the input is not school relevant.	*Participants:* 15 teachers from different types of school. *Cooperation:* The teachers work in school pairs or alone. The researcher (supervisor of Jane) instructs the teachers and discusses the competency model in detail. The teachers develop the materials not only during the meetings but mostly as 'homework'. *Rules:* There are no explicit cooperation rules. An implicit rule is 'reliability', i.e. that someone will do his

	Division of labour: There are group leaders among the teachers, who dominate the process. The researcher Kim is responsible for new (theoretical) input and for literature research. The coordinator is a teacher mentor who 'translates' the teachers' wishes and the researcher's demands.	*Division of labour:* The teachers behave like consumers. They are not very active in the production of new ideas. The ideas and concepts come mostly from the researcher Sarah. The coordinator is a well-accepted experienced teacher who sees herself as participant with non-extraordinary rights.	'homework' in time. *Division of labour:* The teachers develop building blocks for teaching and learning in school pairs or alone. There is only little exchange of materials among the participating schools. The supervisor dominates the teachers; the doctoral student Jane and the Post-doc Anne are his assistant researchers. The coordination is done by an experienced teacher.
Initial objects	*Units:* Bioethical themes like 'Pregnancy and abortion' or 'Organ transplantation' Typically, the teachers decide the context of the teaching units since here they are experts. The input of the researcher is about the competency model.	*Units:* Learning on stations about 'How to investigate a river?' or 'Which pet suits me and my life?' Typically, the researcher develops 'example units' and the teachers are responsible for the further development.	*Units:* Historical experiments about 'food conservation', 'photosynthesis'. Typically, the teachers develop short teaching units that 'translate' the competency model into practice in a focused manner.
Mediating artefacts	Syllabi and curriculum plans Student relevant learning contexts		

Table 3. Analysis of the sub-system 'Researcher'

Sub-system	LC 1	LC 2	LC 3
Researcher	Kim	Sarah	Jane
Similarities	Junior researchers and PhD students Aged 26 – 30 2 -3 years of teaching experience		
Community	Kim is member of a high-level research group, a graduate school, which supports her, especially in methodological issues. Her supervisor allows (or forces) her to foster autonomy and responsibility in the work with the LC 1 teachers.	Sarah is member of a research community consisting of her supervisor, a student partner and an educational graduate school. She has a special feeling for the demands of the teachers. Therefore, during the lifetime of LC2 her specific role in the LC2 changed from an assistant researcher to a well-accepted teachers' partner.	Jane's research community is dominated by her supervisor and a female postdoc. Jane receives much support from them but there is much dependence. Jane never leaves the role of an assistant and she is not really accepted as a researcher by the teachers.
Initial objects	Competence model 'valuing and decision- making	Competence model 'valuing and decision-making in environmental education for	Competence model 'knowledge acquisition in

	regarding bioethical issues'.	a sustainable future'.	the field of experimentation'.
Mediating artefacts	Example tasks *Bik* guideline for the development of tasks		

Boundary crossing in bik LCs

To analyze the processes of teachers and researchers in the *bik* LCs we use Engeström's Expansive Learning Cycle by identifying differences among the LCs regarding the identification of initial questions, the modelling of solutions, the reflection on the process, and the consolidation of new practice (Engeström, 1999).

Questioning. The initial questions of the teachers in LC1, LC2 and LC3 were about the 'new idea' of the *bik* innovation. Kathy and Susan asked for guidelines and 'cooking recipes' for the promotion of students' competences. Joe asked critically 'if there is any evidence that the competency-oriented approach is more successful than clear instructions.' The LC1, LC2 and LC3 researchers developed example tasks to make their competency-models discussable.

Analysis. These example tasks were the analysis units in the three LCs. The teachers discussed them during the LC meetings. They compared them with tasks they had traditionally used, and debated the tasks' possible learning outcomes and how the outcomes could be assessed. In LC 1 and LC 3, teachers who worked in different school types analyzed the practicability of tasks by considering the task performance in the specific school type.

Modelling new solutions. The discussions about practicability and assessment of the *bik* example tasks led to a phase of intensive production. The teachers developed new classroom materials. These materials had to be in line with student-relevant contexts and modelling competencies. Two points were remarkable: the teachers needed a longer period of time (about two to three months) to develop the first 'products' – tasks that were to be tested in the classroom. The second point was that in LC 1 and LC 2 the discourse of task development led to a power struggle among the participants and to the establishment of sub-groups. In LC 3 the researcher gave 'homework' to the teachers where they developed 'building blocks' at home and exchanged them via e-mail.

Examining the models. In the next step the newly developed tasks and units were discussed in the school teams and examined in the school classes. During the following LC meetings the classroom experiences were discussed. The researchers supported the classroom reflection by offering 'reflection sheets'. The willingness to discuss classroom experiences was higher than the willingness to write reflections. In all LCs the examination of the self-developed classroom materials led to a new prospering phase: in groups (LC1), in school teams (LC2), or in groups and by individuals (LC 3) a large number of materials were developed and tested.

Modelling new solutions. The above led to a second phase of modelling new solutions: the researchers of the LCs came together and developed a mutually shared guideline for the development of *bik* tasks. In annual meetings the teachers demonstrated their developed materials and discussed the practicability, assessment and possible impact of the *bik* tasks.

Implementation of the new model. The *bik* materials were disseminated via an internet platform and a CD Rom. The *bik* LCs invited researchers of other LCs to come to their meetings and to inform them about further competency models (e.g. the researcher of LC3 was invited by the teachers of LC2 to introduce them to the competency model of experimentation). During the annual meetings, teachers informed teachers from other LCs about their work in *bik*, and conducted workshops where they informed about, discussed, and negotiated different *bik* conforming teaching and learning approaches

Reflection on the process. The systematic reflection on the negotiation process or on the experiences during the LC meetings and the classroom experiences was a great challenge for the participating teachers. The reasons given were mostly a lack of time or 'the belief that reflection is not necessary for one's own professional development' (final interview with teacher Joe). Therefore, the guideline for *bik* task development was used as a reflection tool. With this tool each task could be analyzed to ascertain to what degree the *bik* goals had been reached.

Consolidating new practice. The *bik* outcomes were at different levels. The teachers reported 'awareness of new ways of teaching and learning' and 'new ideas'. Most of them stated their intention to implement the *bik* ideas in their classrooms, but only a few teachers changed their classroom practice fundamentally.

Further outcomes of the boundary crossing process

Changes in teaching practices. The teachers reported several motives for the change of practice. The three investigated teachers, Susan, Kathy and Joe, reported the intention to do things differently in the future (e.g. to be more aware of the students' interests, to foster students' communication skills), and the intention to continue new practices. The teachers usually expressed this intention when they had just tested and experienced a classroom experiment successfully. Although the teachers *intended* to change their practices, they rarely reported actual *changes in the classroom*. For the analysis of 'changes' we distinguish 'changed practice' from 'temporary experiments'. Only Joe reported that he had changed his practice in a more permanent way and not just for a few lessons (Joe's report). Kathy and Susan reported that they had not used the new teaching and learning approach often because 'teaching bioethical dilemmas is only for a few lessons' (Kathy's final interview) and 'students like my lessons about decision-making regarding environmental issues. They make positive remarks, but – on the other hand – I have to continue to teach according to the current syllabus' (Susan's final interview).

Changes of the competency models. In the three *bik* LCs investigated the initial competency models were changed. These changes were caused by the models' practicability and their statistical validation. In all cases the models were simplified by reducing their complexity. The reduction of complexity made the competency models easier to handle for the teachers' task development. In each LC, guidelines on how to plan tasks and units according to the competency models were developed.

CONCLUSIONS

Summarized, for the analysis of the processes within the *bik* Learning Communities, Engeström's activity theory has proved of value as a heuristic for the interactions and processes of mutual learning. The main outcome of the study is a better understanding of the elements and dynamics of the activity systems including the mutual learning process of all participants around context- and standards-based curricula (Elster, 2012).

Traces of mutual learning. The transformation of the *initial objects of teachers and researchers* (objects 1) to *finalized teacher-researcher objects* (object 2) allows the identification of traces of mutual learning: The *finalized objects* (object 2 in Figure 1) are the concrete products of the negotiation of teachers and researchers. In LC1 these are tasks and units for decision-making in bioethics (e.g. embryo transfer, medically-assisted suicide) in new student-relevant contexts. In LC2 these are tasks and units in environmental education and sustainability based on a guideline for ethical decision making. In LC3 these are building blocks to foster the competences needed for conducting experiments (generating research questions and hypotheses; planning an experiment; drawing conclusions from the experiment). Furthermore, in LC 3 a complex concept for individualization based on materials about subject-related communication is developed.

Implementation of an educational reform. Educational innovations and the implementation of educational reforms succeed or fail not only because of the teachers as 'targets and agents of change', but also because of the researchers who are shaping the reform. In the three investigated *bik* Learning Communities the 'symbiotic implementation approach' (Gräsel & Parchmann, 2004) leads to the mutual sharing of experiences and concepts, and the establishment of a win-win relationship of teachers and researchers. Based on this relationship the teachers act as partners in the educational reform of the implementation of National Educational Standards in schools. This is considered as one of the traces of success of the *bik* innovation.

ACTIVE STRATEGIES DURING INQUIRY-BASED SCIENCE TEACHER EDUCATION TO IMPROVE LONG-TERM TEACHER SELF-EFFICACY

Robert H. Evans[1]
[1]Department of Science Education, University of Copenhagen

Abstract: Teacher development aimed at increasing the use of inquiry based methods in schools is an important way to reach science learning goals. To this end, the EC has promoted inquiry based science teaching (IBST) within the Seventh Framework Program (FP7). One dimension, typically absent from the FP7 products, is the personal capacity belief of self-efficacy which has been shown to be important to personal behavioral change. The purpose of this research was to develop and test a model of teacher professional development (TPD) which adds specific elements for altering teacher self-efficacies to existing FP7 IBST products. This model was tested for its usefulness in increasing participant self-efficacy as evidenced by short and long term quantitative measures as well as by evaluation of long term inquiry lessons. Workshops to promote IBST were conducted in five different countries. Each workshop included strategies for increasing participant's self-efficacies. Pre and post assessments showed consistently improved personal self-efficacy scores in all of the workshops. In addition, and unlike other long-term studies of teachers, these self-efficacy scores did not significantly diminish over six months. The promotion of self-efficacy in TPD provides a consistent way of evaluating the impact of IBST workshops through the use of changes in self-efficacy.

Keywords: self-efficacy, inquiry, teacher development, long-term

BACKGROUND, FRAMEWORK AND PURPOSE

With dissemination of the results from the TIMMS (Gonzales, P., et al., 2008), PISA (OECD, 2010) and ROSE (Sjøberg, S. & Schreiner, C., 2010) studies, calls for enhanced science teacher professional development in Europe have become more urgent. Improved teacher education both in curriculum and pedagogy has been a suggested response to a lack of student interest and performance among large percentages of secondary science students (Osborne, J. & Dillon, J., 2008). Simultaneously, teacher development aimed at increasing the use of inquiry based methods in schools has been forwarded as an important way to reach these pedagogical goals (see for example, Rocard, M. et al., 2007). Partially in response to these calls for change, the European Commission has promoted inquiry based science teaching (IBST) within the Seventh Framework Program (FP7) through various projects. The plethora of useful materials developed by these and other projects all rely on effective teacher professional development (TPD) to sustainably inculcate science teachers with advanced IBST methods. To accomplish this, the projects typically rely on workshops where teachers are 'trained' in the use of the new materials with more and less success given the difficulties inherent in changing teaching cultures and procedures.
However one dimension, typically absent from TPD from the FP7 products, is the personal capacity belief of self-efficacy which Bandura (1997) has shown to be important to personal behavioral change. While research has not proven a causal relationship between self-efficacy and teaching competence, significant correlations between high teacher self-efficacies and the amenability of teachers to even attempt innovative methods have been found (Ashton & Webb, 1986; Smylie, M.A., 1990). Consequently, incorporating capacity belief change into

professional development programs seems like a worthwhile addition to the FP7 product workshops.
The purpose of this research was to develop and test a model of teacher professional development which adds specific elements for altering teacher self-efficacies to existing FP7 IBST products. This model was tested for its usefulness in increasing participant self-efficacy as evidenced by short and long term quantitative measures as well as by evaluation of long term inquiry lessons. It was hypothesized that self-efficacies could be increased through active influence and inferred that increases would help teachers carry the workshop lessons more successfully back to their teaching.

RATIONALE

Bandura (1997) showed that people act not only because they believe their actions will result in specific outcomes but also because they believe in their own ability to perform them. In science teaching, teachers with high self-efficacies are more likely to use inquiry and student centered teaching methods while those with low efficacies were more likely to be teacher directed (Czerniak, 1990).

Since teaching self-efficacy most typically declines between workshops or pre-service coursework and a year or more of teaching (Andersen, 2004) consequently, actively influencing self-efficacy during TPD may act to retain higher self-efficacies over time. Bandura (1997) established three basic mechanisms by which teacher self-efficacy may be influenced. The most important of these is 'enactive mastery experience' where success in teaching with unfamiliar methods, inquiry science for instance, reinforces future teaching. Also influential are 'vicarious experience' in which emulating the successful teaching of comparable others impacts self-efficacy as does 'verbal persuasion' in the form of credible feedback.

Active use of these mechanisms for changing teacher self-efficacy has been advocated by Bandura (1997) and others, but few studies have controlled and measured consequent effects. Bautista (2011) made extensive use of vicarious and mastery experiences to influence the self-efficacy beliefs of elementary education pre-service students. He did not use 'verbal persuasion' since he found it difficult to measure and control during a semester course. He found significant increases in self-efficacy during the study.

METHODS

Teacher professional development workshops to promote inquiry based science teaching for both pre-service and in-service science teachers were planned and piloted in five different countries. A total of 70 teachers participated in the workshops, each of which lasted from one-half to one and one-half days included strategies for increasing participant's self-efficacies. These methods using Bandura's three basic strategies for influencing self-efficacy were as follows:

Enactive Mastery Experiences

- During the workshops, participants originated and taught short inquiry lessons to their peers. They received peer-written and verbal feedback about the successful elements of their lessons as well as suggestions for improvement. In the relatively safe and supportive environment of a peer workshop, most had a successful experience with inquiry teaching.

- Participants revised traditional non-inquiry science lessons during workshops and shared their revisions with others. The affirmative feedback they received from the group about their ability to adapt traditional material to an inquiry format was part of a mastery experience.

- All were encouraged to use their developing inquiry teaching skills after the workshops with their own students. In one instance a six-month follow-up workshop was held and participants brought video of themselves teaching an inquiry lesson to their own class.

Vicarious Experience

- Each workshop included examination and analysis of short video segments of science teachers from three different countries teaching lessons which included elements of IBST. Since segments were selected to be realistic with typical teachers, participants could identify with the teachers and imagine themselves also able to do IBST teaching.
- Since each teacher taught a short 'invitation to inquiry' lesson to the workshop participants, each also got to see peers teaching successfully with IBST methods.
- The workshops were completely taught using IBST. To the extent participants could identify with the instructor, they could vicariously imagine themselves also using IBST.

Verbal Persuasion

- During participant IBST teaching, both to the workshops and in one case to their own students, their peers and instructor emphasized the successful elements of their lessons and offered ideas for improvement.
- Feedback to transformed traditional lessons from both peers and the instructor focused on changes consistent for IBST and offered credible further alterations.

Quantitative measures of self-efficacy were made of all participants using the widely used STEBI instrument (Enochs, L.G. & Riggs, I.M., 1990). Both pre-and post-workshop measures of self-efficacy were taken. In the long-term follow-up workshop where participants shared videos from their own classes in which they taught using IBST, self-efficacies were again measured. Observed instances of inquiry teaching both live and via videos were scored for inquiry based on the Science Learning Cycle Rubric developed by Goldston, M.J. et al. (2010).

RESULTS

Participant feedback from the workshops was classified according to Bandura's three basic strategies for influencing self-efficacy. Their comments begin to validate the method of active self-efficacy enhancement in that the participants recognized personal benefits from each of the three strategies. These are examples of the grouped comments:

Participant comments relating to enactive mastery experiences

'The preparation leading up to making the video involved a lot of discussion and planning. As a result I felt that it pushed us to explore the area more deeply. This is a good thing. I think this stage was a good one if the time is available to do it properly.'
'Really good! Yes, such elements should be part of every teacher's education. Working in small groups on preparing has amazing affects on deep discussion of goals and means to achieve them.'
'To feel your own body, what works and what captures you.'
'Always useful because it gives experience. Feedback was good! '
'Involving! Group discussions result in good ideas.'
'This was useful. It is about making it practical and discussing it.'
'Important to try oneself- having to think a bit further. Something that we are not always good at.'
'Useful to find own examples. Easier to change my own teaching after this.'

'Own experience and discussions after words were useful. Good to see what others do … gives ideas.'
'Liked the idea with a way of reflecting on the steps I do things like body language and voice.'
'Effective and to the point! Performance is reformed by seeing ourselves in action with these goals. It was just 'perfect'. Teachers were natural.'
'Fun to test yourself under pressure.'
'Good thing so less confident people get to experiment with their teaching style. But go to live teaching shortly afterwards.'

Participant comments relating to vicarious experiences

'*The videos worked really well. Communication in the classroom is very rich and the videos captured this, particularly the dynamic aspects.'*
'Videos are very good for discussion so keep those in the modules. Instruction was clear and time sufficient.'
'It is useful to have an example in common to talk from.'
'Fine to see real teachers in real situations. Good that it is not results we see but something to discuss.'
'Ok to start discussions…nice to see 'real' teachers and pupils.'
'I learn how to do it by watching. How to spend time and talk to students.'
'A concrete starting point for discussion.'
'Examples of unknown teachers allow free and open discussions of good and bad.'
'Good way to have a common things to talk about. Easier to begin with others.'
'Very useful. Group work was very beneficial to apply things.'
'To see what is good teaching and what is not. See how students react to both kinds. Discussing how to make bad teaching better. It was all great and very useful. Most interesting and best part of the day.'

Participant comments relating to verbal persuasion experiences

'Always useful because it gives experience. Feedback was good! '
'Own experience and discussions after words were useful.'
'Liked the idea with a way of reflecting on the steps I do things like body language and voice.'
'Good thing so less confident people get to experiment with their teaching style.'

Relative scores on the self-efficacy instrument varied between workshop participants along with their teaching experience and cultural milieu. Quite consistently in all of the workshops however, pre to post workshop scores increased regardless of the original scores. Since the long-term effects of IBST workshops are of particular interest, a group of participants in such a workshop were followed and examined as case-studies. In these cases, pre and post STEBI scores were taken at the start and conclusion of a two-day workshop and again six months later at a follow-up workshop. In addition, participant videos of teaching in their own classrooms were scored. An example of two of these followed cases:

Participant A. During this in-service teacher's participation in the original two-day workshop their relatively high STEBI scores went from 100 to 104 and in the follow-up workshop eight months later, remained relatively high at 106. Consistent with this stability was the rating of 7.5/10 on a video of his teaching. They showed particular strength in providing continuous feedback to the students as they 'inquired' and in maintaining a 'learning cycle' sequence to his lesson. The teacher's students were engaged in an exploration of content which required original thinking in non-formulaic ways. With minimal instructions and an acceptance of varied solutions, the teacher gave the students opportunities for genuine inquiry and rewarded their efforts by using their solutions for the problem resolution. The teaching was very consistent with the workshop aims.

Participant B. This teacher's relatively low self-efficacy score compared to the group went from 84 to 88 during the initial two-day workshop and was stable at 87 in the eight-month follow-up. However, the teacher's inquiry teaching video was rated at 7.0/10 based on a particularly strong student engagement using real world links to student's daily lives. The teacher also had a good extension and feedback. However, the teaching was notably weaker in the inquiry exploration and explanation.

CONCLUSIONS AND IMPLICATIONS

The use of active strategies to enhance self-efficacy during workshops has been validated through pre and post assessments which showed consistently improved personal scores in all of the workshops. However, unlike a previous long-term study of teachers, this study's self-efficacy scores in the long-term instance did not significantly diminish during the intervening six months (Andersen, A.M. 2004). If through repetition, the active uses of Bandura's (1997) methods for increasing teacher self-efficacy prove to be effective, then their wide-spread addition to IBST modules may be validated. This on-going study's results also provide a consistent multidimensional way of evaluating the impact of IBST workshops through the use of changes in self-efficacy of participants as well as success at using inquiry after workshops back in classrooms. Both outcomes would increase the efficacy of workshop products of EC projects.

SO WHAT IS IT? MAKING SENSE OF THE COMPONENTS THAT CONTRIBUTE TO EFFECTIVE PRIMARY SCIENCE TEACHING

Angela Fitzgerald[1]
[1]Monash University, Melbourne, Australia

Abstract: Teachers are key players in the reinvigoration of science education. Unfortunately, the spotlight is often shined on the shortcomings associated with teaching and learning in science. If the status and quality of science education in schools is to improve, efforts need to be made to better understand the classroom practices of effective science teachers.

In a step towards better understanding, the doctoral study gathered evidence examining what two effective primary teachers were doing to promote student engagement in science over a term long sequence of lessons. Evidence of their effective science teaching was gathered primarily through a video-based approach and was supplemented with teacher and student interviews, and student work samples.

Several themes were identified as characterising the practices of these two teachers. These themes form the basis of a conceptual model, which was developed to highlight the various components contributing to effective primary science teaching practices. In teasing out these components, this paper will examine how the teachers' beliefs, knowledge and practices, as well as the contextual factors inherent in their classroom environments, influenced how and why they teach science in the ways they do. While care must be taken in generalising from two cases, these findings have implications for primary science teachers, teacher educators and curriculum developers.

Keywords: primary science education, effective practices

BACKGROUND, FRAMEWORK AND RATIONALE

With trends across many countries still indicating the decline of student interest in school science and diminishing numbers of students studying science beyond the compulsory years, it seems that the field remains in crisis. In recognition of the impact that teachers have on student learning (Hattie, 2003), changes to this situation would need to come from teachers who are qualified and committed to science (Goodrum, Hackling, & Rennie, 2001). If these changes are to be realised, an understanding of what constitutes effective science teaching is required and should be addressed.

Reflecting the context of this study, there are three key research documents that have identified characteristics of effective science teaching in Australian schools. These documents are the *National Review into the Status and Quality of Science Teaching and Learning in Australian Schools* (Goodrum et al., 2001), the *Professional Standards for Highly Accomplished Teachers of Science* (ASTA and Teaching Australia, 2009), and the components of effective science teaching as developed by the *School Innovation in Science (SIS) Project* (Tytler, 2003). These three documents provide rich, detailed descriptions of what characterises the strategies, attributes and environments of effective science teaching practices. The frameworks that these studies provide are useful tools in better understanding the different aspects of effective science teaching and learning. In their synthesis of these documents, Hackling and Prain (2005) identified a strong convergence around six characteristics of effective science teaching:

1. students experience a curriculum that is relevant to their lives and interests;
2. classroom science is linked with the broader community;
3. students are actively engaged with inquiry, ideas and evidence;
4. students are challenged to develop and extend meaningful conceptual understandings;
5. assessment facilitates learning and focuses on outcomes that contribute to scientific literacy; and
6. information and communication technologies are exploited to enhance learning of science with opportunities to interpret and construct multimodal representations.

(Hackling & Prain, 2005, p. 19)

However, while these identified components may help to shed light on the nature of effective science teaching, on their own they cannot bring effective science teaching to life. Effective science teachers may be able to demonstrate particular attributes, but little is understood about precisely what beliefs and knowledge drive their practice. Therefore, it is not clear why effective teachers' actually do what they do.

The overall purpose of this doctoral study was to collect evidence about what effective primary science teaching looks like over a term long sequence of lessons and to explore the relationships existing between teachers' beliefs, knowledge and their practice. This paper will report on the findings gathered from two primary school science teachers involved in this study, Deanne and Lisa. In particular, the following research question will be addressed: what characterises the practice of an effective primary science teacher?

METHODS

This study was qualitative in nature and incorporated ethnography with an interpretive case study approach (Merriam, 1998). These methods were used to reflect the complexities inherent in teaching and in coming to better understand the practice of teaching, as well as to allow for the recreation of a rich and vicarious experience for the reader (Peshkin, 2000). This section provides an overview of the research design used for this study by outlining the participants and data gathering techniques used during the data collection process.

The participants in this study were two primary school teachers, identified as effective practitioners of science by a professional colleague, and their students. At the time of the study, Deanne was teaching a Year 7 class and Lisa was teaching a Year 3 and 4 class. Year 7 is the final year of primary school in Western Australia, the Australian state where this research was conducted. A focus group of four students was formed in each class.

Observations were carried out in each teacher's classroom over one school term (10 weeks) during their weekly science lessons (each approximately one-and-half hours in length). Three video cameras captured each science lesson with one camera tracking the teacher, one camera focused on the focus group students, and the other camera was fitted with a wide-angle lens to focus on the whole class. Following each classroom visit, semi-structured interviews were conducted with Deanne and Lisa with each interview approximately 40 minutes in length. The focus group students from each class were also interviewed after each science lesson. These students were interviewed as a group with each interview taking approximately 10 minutes. Written documents were also collected from the two teachers and their students over the unit, such as unit plans, worksheets, assessment items and work samples.

The data collected from the multiple sources were examined for the practices characterising Deanne and Lisa's approaches to science teaching and learning. A process of ethnographic microanalysis, as described by Erickson (1992), was used to analyse the data from the video footage, interview transcripts, and work samples. Data sources were watched or read several times and events, episodes and quotes were identified that provided supporting evidence for the emergent themes. Several themes emerged from the data and were identified through being mentioned or observed numerous times. The emergent themes were presented to both teachers for further clarification.

RESULTS

This research resulted in five general assertions (GA) being developed to describe the influence of effective science teaching practice on student learning in science. These five general assertion were:

- GA 1: Teaching for student engagement in science;
- GA 2: Providing students with concrete experiences in science
- GA 3: Supporting student learning in science
- GA 4: Monitoring students' learning in science
- GA 5: Developing scientifically literate students

The model below (see Figure 1) was synthesised from the general assertions that emerged from the analysis and interpretation of the multiple data sources. This representation identifies the interacting components that characterise the similarities inherent in the effective science teaching practices of the two teachers.

The components of the model are described, in relation to the five general assertions, in the following text. Deanne and Lisa used concrete experiences of science to provide students with opportunities to explore science phenomena first-hand (GA 2), engage in meaningful talk about science (GA 3) and provide a context for the construction and use of multi-modal representational forms (GA 3). They actively monitored these learning experiences and provided students with constructive feedback regarding their learning (GA 4). These components are embedded within inquiry-based approaches to science teaching and learning, which acted to promote student interest and engagement (GA 1). Through nurturing student understandings and positive attitudes towards science (GA 1), Deanne and Lisa supported students in becoming scientifically literate citizens who are capable of engaging with science issues relevant to their lives and their communities (GA 5). Underpinning these practices are beliefs, knowledge and contextual factors, which directly impact on teachers' orchestration of learning to meet their particular students' needs in the contexts in which they work.

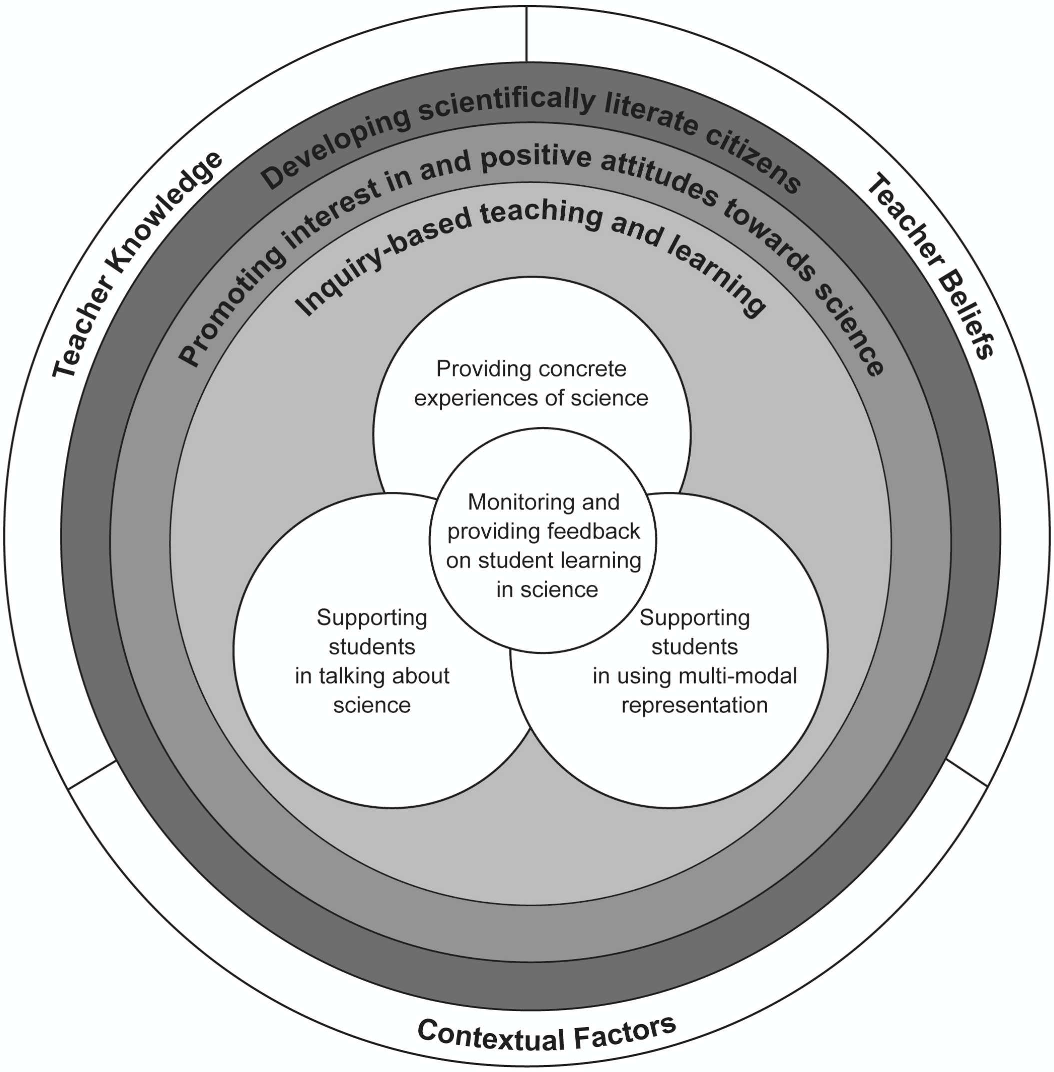

Figure 1. Conceptual model of components contributing to effective primary science teaching

CONCLUSIONS AND IMPLICATIONS

The tendency for primary school teachers to avoid the teaching of science has been well documented (e.g., Tytler, 2007). Research has suggested that as little as three per cent of teaching time, on average, is allocated to the teaching of science in Australian primary schools (Angus, Olney & Ainley, 2007). Other research has demonstrated that interest in and attitudes to science learning are entrenched in 14-year-old students (e.g., Lindahl, 2007). When combined, these findings concern all stakeholders in primary science education. The primary school years are therefore a crucial time for capturing students' interest in science and the development of understandings of what constitutes effective science practices in the primary setting are of key importance. While this research contributes to the existing knowledge base and literature, a more comprehensive understanding of what constitutes effective primary science teaching and how it is influenced by teachers' beliefs and knowledge, as well as contextual factors, is needed if we are to better support primary school teachers in the practice of teaching science.

INNOVATIVE SCIENCE TEACHERS: WHAT THEY HAVE IN COMMON

Paulo Sérgio Garcia[1]
[1]Faculty of Education - University of São Paulo - Brazil

Abstract: Changes, in general, in science education require that teachers play an additional role different from their traditional model. However, in Brazil teacher education policies do not provide the necessary conditions for changing the role of the teacher. In the Brazilian context, at least for public schools, science teachers do not have many opportunities for innovative practices as there are a number of factors that can prevent it from occurring. Nevertheless, even in this unfavorable context, some science teachers create new ideas (e. g. curriculum development projects), and innovate their pedagogical practices. This study seeks to identify professional characteristics of innovative science teachers that even without support or time, they innovate their pedagogical practices. We used different research techniques including open-ended and narratives interviews (2010) and participant observation with two science teachers from elementary schools. The teachers were observed for three years (2008-2010). The data showed that these professionals have some characteristics in common: they create innovations by themselves; participated in new school' curriculum development projects, they regularly participated in continuing education programs, they were more motivated to enhance their daily pedagogical practices, and they had a social commitment to students. Understanding these professional characteristics can assist school principal and pedagogical coordinator to promote, encourage, and support science teachers in creating and participating of innovation.

Keywords: Innovation. Changing. Science teachers.

INTRODUCTION

Changes in science education require that teachers play another role different from a traditional way of teaching. However, in Brazil the teacher education policies do not provide the necessary conditions for changing teachers' practices. Thus, science teachers in most classrooms do not innovate and change their pedagogical practices, related primarily to traditional content exposure, and the use of traditional pedagogical tools such as blackboards and textbooks.

Innovation is defined as a set of interventions and decisions with a certain degree of intentionality (FULLAN, 2001; CARBONELL, 2002; CARDOSO, 2003). According to Carbonell (2002) it can be used to stimulate theoretical reflection of the teachers' experiences and promote interactions among students.

Many factors influence innovations. Among them are: culture of school, teachers' conceptions regarding teaching and learning.

In another study (Garcia, 2009) it was demonstrated in a Brazilian context that some factors prevent science teachers practicing innovation (e. g. lack of time to discuss the problems of implementation and the development of innovation in school). This is opposite to the simplistic view from that tend to blame science teachers for lack of innovative practice. Others factors that also prevent innovations are the poor working conditions, new laws that overload teachers' practice with more assignments and responsibilities, traditional pre-service education program, the role of principals in schools, and the teachers general lack of knowledge and beliefs in innovations being proposed.

Nevertheless, even working in unfavorable contexts for change some science teachers seek new alternatives, and in fact do innovate.

We believe, as Cardoso (2003), that there are many variables involved in the process of teacher-as-innovator. These include: *organizational factors* (those linked to encouraging climate that can favor personal initiative), *professional* (those related to professional activities); *personal* (those linked to teacher' attitudes related to innovation receptivity) *demographics* (gender, age, work experience), and *personality* (linked to a greater or lesser predisposition to innovation).

In this study we are particularly interested in identifying professional characteristics (variables) that are common about science teachers' daily pedagogical practices. Understanding these professional characteristics can assist school principal and pedagogical coordinator to promote, encourage, and support them at school, favoring, in this way, science teachers to create and participate of innovation.

TEACHERS AND INNOVATIONS

Despite its ambiguous character, innovation refers to a set of interventions and decisions with a degree of intentionality and systematization, which aim to transform attitudes, ideas, culture, content, pedagogical models and practices (FULLAN, 2001; CARBONELL, 2002; CARDOSO, 1997).

The implementation of innovations, according to Fullan (2001: p. 75-80), is affected by a set of interactive features. Among others, is the need for change and clarity about the goals and objectives. Innovation also depends on the culture of the school, the teachers' conceptions about teaching and learning, and still need time and support to be implemented.

In recent years, reforms and innovations implemented by governments have failed to transform, for example, science teachers' practices that continuing being traditional. This is because, in part, in Brazil policies for teacher education have not produced the necessary conditions for a significant change in the role of the teacher. Many science teachers, however, have the desire to change, but they are working in systems, schools, and with professionals who do not promote innovation, and often even functioned as obstacles to change (GARCIA, 2010).

Some authors have already identified some obstacles related to innovation. Among them are the overload of work (HARGREAVES & FULLAN, 2000), individualism of the profession (HARGREAVES & FULLAN, 2000; THURLER, 2001), organization and operation of the school (THURLER, 2001), the meaning of innovation (HARGREAVES, EARL & RYAN, 2001; THURLER, 2001, FULLAN, 2001), the issue of time to perform the change (HARGREAVES, EARL & RYAN, 2001; CARBONELL, 2002; FULLAN, 2001), lack of support for teachers make concrete changes (FULLAN, 2001; CARBONELL, 2002), the way the school principal work (THURLER, 2001), the reflection of failed innovations on future projects (HARGREAVES & FULLAN, 2000; THURLER, 2001), lack of time to discuss the problems of implementation and the development of innovation in school (GARCIA, 2009).

Garcia (2009, p.55) identified some factors that difficult science teachers to innovate: personal factors (lack of interest in participating in the project, fear, insecurity), professionals (lack of encouragement, support and time, inability of those who run the project, overwork and lack of learning) and contextual (lack of material and financial resources).

However, it is worth noting that some science teachers, even working in some unfavorable contexts with many obstacles, as described earlier, they still innovate in their classrooms. They have a change as an integral part of what they believe in their work. Create new practices, being receptive to others, participate in projects is part of what they believe about teaching and learning. In other words, innovation is part of their personal views of teaching and learning in schools.

Beside this, in a study about pedagogical innovations at the university, Cunha (2004) showed that teachers who innovate have some common characteristics. They enjoy teaching, are dedicated to their work, more enthusiastic about their practices, more critical and satisfied with what they do, and have a social commitment to students and to school community.

Cardoso (1999), on the other hand, tried to understand the correlation between teachers' receptivity to innovation associated with other variables such as experience in teaching and continuing education. The author found, although weak, positive correlation between continuing education, (in terms of participation in courses (congresses, conferences), publishing scientific articles, and research projects inside and outside the school), and receptivity to innovation. That is, teachers with greater participation in these three levels also had more favorable attitudes to pedagogical innovation.

METHODS

This study aims to identify common professional characteristics in two science teachers who innovate constantly in their teaching practices. To answer this question we selected two science teachers who work in elementary education in public schools in Sao Caetano do Sul, a province/state near Sao Paulo - Brazil.

These two teachers were selected from a group of 20 teachers who taught in elementary public schools. Our choice was based on their classroom performances in schools and specifically their teaching of science classes. These teachers regularly created innovative pedagogical practices, participated in other school-based initiatives, they were constantly involved in continuing education, and also involved in activities with their students, which included field trips.

Data were collected through participant observation and interviews. It is worth noting that the researcher was also the responsible for promoting science continuing education for these two teacher participants and, therefore, spent three to five hours per week with them.

The observations were conducted for approximately three years, once a week (on alternate days) for duration of two hours. The observations were made using protocols of research adequately developed to collect information on: 1) number of innovations created, 2) participation in the school's innovations, 3) participation in continuing education projects, 4) involvement with students, 5) involvement with parents, and 6) professional connections.

The interviews (2010) collected information on 1) teachers’ profile (gender, age, education, teaching experience, teacher workload, per week), and 2) on the teachers’ triggering reasons to innovate. Narrative interviews were also conducted in order to understand more about their personal and professional trajectories, however these data are still being analyzed.

We also interviewed:

- A) a group of 10 students about these two exceptional teachers in 2008, 2009, and 2010 (different students each year) to know: 1) students' view over his/her teacher, 2) students' view over his/her teacher' classes (his or her pedagogical practices) 3) students' view over the relationship between them.
- B) the pedagogical coordinator from both schools.

RESULTS AND DISCUSSION

The participants were one male (55 years-old) and one female (45), both with over 20 years of teaching experience. His undergraduate degree majored in Science and Biology, and worked in two public schools and with a workload of 45 hours-class per week. She majored in Science and Chemistry, worked in a public school with 26 hours-class per week. Both had experience with some postgraduate science courses.

From the interviews we highlight the reasons about their willingness to engage in pedagogical innovations. With very similar responses, both research participants attributed this approach to innovation based on their beliefs about education; that is, their conceptions of teaching and learning, which was also confirmed by observations. They valued and believed that innovations could motivate students and at the same time improve their pedagogical practices. This finding was also found by Anderson (1989) when he affirmed that the conceptions act as personal theories that lead, among other things, pedagogical practice of teachers.

From interviews we highlight two other results that are explained below:

She indicated that she could be innovative because the school's atmosphere offered a perfect scenario to create new curriculum and pedagogical projects. He, on the other hand, stated that he used to innovate because that was part of his daily life. This reason may be linked to his personality and not necessarily to his views of education. The narrative interviews which we are still analyzing may explain more about this finding. It is interesting to note that both teachers were enthusiastic about teaching science, and had a social conscious about students as it was already described by Cunha (2004). This commitment was expressed, among other things, meetings with students inside and outside working hours, educational programming outside of school with students, with respect to organizing and supervising visits with students to museums.

Data from observations showed that the two teachers created at least one innovation each year. They also participated in any new school projects being organized during every year of the observations. They were constantly engaged in continuing education in their workplaces. The male participant was involved in independent professional development courses at universities as well. In fact, teachers-as-learner was a permanent characteristic of both teachers. This again confirms what Cardoso (1999) found in her quantitative study about the positive correlation between continuing education and the receptivity to innovation.

Both participants were regularly trying to find new contents from newspapers, scientific journals to bring to their students. They were commonly involved with their students, although he promoted more pedagogical studies outside the school. They knew, for example, students' name, students' difficulties and had good teacher-student relationship with them. They were viewed by their students as being more democratic and good teachers in general. Finally, these professionals had contacts with networks of collaborators outside the school, generally associated with colleges and universities.

The school and the school principal also considered them excellent teachers. They were, generally, in the school staff meeting more critical they asked more questions, and discussed and criticized the ideas that were being discussed.

Interviews with the two pedagogical coordinators (PC) of schools showed that they also considered the two teachers as innovators, because they were always "creating, inventing, taking part in something at school or community" (PC01). One of the coordinators also said that in school meetings the teacher demonstrated to be more critical and has a more elaborate discourse about pedagogical practices (CP02).

FINAL IMPLICATIONS

We highlight some professional characteristics that are common in both teachers: 1) involvement with continuing education, 2) motivation with the pedagogical practices and 3) social conscious about their school community.

These professional characteristics have direct implications for school principals and pedagogical coordinator for the school and school district. School and district administrators can act to promote a better atmosphere to develop, encourage, and support these professional characteristics at school amongst all teachers. This will help science teachers to gain confidence and begin pedagogical and curricular innovations and, at the same time, participate with other teachers with the objective of assisting students in their process of learning science in schools.

On one hand, the implications of those conclusions bring the need to ensure a deep understanding of several variables involved in innovation process. On the other, it indicates that larger investments in the quality of science teachers' initial and continuing education especially in support to school-based professional development, may favor science teachers in the process of creating innovative pedagogical practices.

HOW DO IN-SERVICE TEACHERS EVALUATE THE COGNITIVE/LINGUISTIC SKILLS IN THE STUDY OF ASTRONOMY?

Susana García-Barros & Cristina Matínez-Losada[1]
[1]A Coruña University –Spain-

Abstract: The aim of this study is to find out how teachers of the last years of Primary and the first years of Secondary evaluate and what difficulties they find in relation to a series of cognitive- linguistic skills (description of facts and observable phenomena, description of theoretical models and justification of the phenomena using theoretic models). It also aims to find out whether teachers establish differences when the skills are expressed in a general sense or when they are associated to the subject of astronomy.

In the study, 113 Primary and Secondary teachers from different centres in Galicia (Spain) who responded to a closed survey took part. The results show that the teachers positively evaluate the skills presented, with changes being seen in terms of content. The description of facts/phenomena is considered more in generic terms and those skills which require more abstraction, in astronomy terms. The teachers attribute more difficulty to the latter skills in the generic principles than in the astronomy ones.

The few differences between the groups of teachers are in the evaluation of the description of models and in the difficulty attributed to some skills that require more abstraction from the primary group.

Keywords: Teaching thought. Active teachers. Primary. Secondary. Astronomy

INTRODUCTION

Communication is very relevant in the teaching of sciences (Jiménez Aleixandre, 2003; Mortimer, 2006). For this reason, the development of different cognitive-linguistic skills is important, such as for example: the description of a fact or phenomenon; of a theoretical model and the justification which explains why this phenomenon is produced, by using an accessible theoretic model with students of a certain age (Jorba et al., 2000). They are all necessary and they should be promoted in different subjects in a balanced manner. There is no sense in teaching a model if it is not going to be used in order to justify an act/phenomenon.

In particular, in the subject of astronomy the description of the models (Earth rotation/ passage) is insisted on more than the observation of the sky. Teachers may feel uncomfortable focusing their attention on the direct observation of the movement of the stars throughout the day and night as this involves carrying out a geocentric interpretation. Therefore, it is immediately clear that what we observed is not “right” (Shen & Conferí, 2010). However, despite the importance that teaching staff seem to give to knowledge of the theoretical models, they have difficulty in working properly with the model in the classroom (Justi & Gilbert, 2002).

The teachers' way of thinking is an important factor in the change and improvement of teaching, therefore knowing their opinions is essential for improving their professional development and the quality of teaching (Van Driel, et al. 2001; Mellado, 2003).

In accordance with the aforementioned, our objective is to find out how practicing teachers in the last years of Primary and the first years of Secondary evaluate certain cognitive-linguistic skills when they are expressed in generic terms and when they are associated to astronomy content. We also intend to find out the difficulties the teachers attribute to these skills.

METHODOLOGY

A closed survey was carried out of 113 practicing teachers (59 from the last year of Primary (students from 9-11 years old) and 54 from the first year of Secondary (12 to 14 years old), from different schools in Galicia (number of teachers per centre always <3).

The participants evaluated on a scale of 1 to 5, the importance and difficulty of some language-related skills: description of facts and/or phenomena, description of a theoretic model and their justification. The skills were stated generically and they were associated to their knowledge of astronomy. Specifically, the teachers had to evaluate the importance and difficulty of generic abilities expressed in the following terms: a) "describe facts and natural, observable, everyday phenomena, such as the movement of objects, changes of state, rainbows, etc."; b) "describe un-observable processes, such as digestion in human beings, or describe more or less simple scientific models, such as a model of a cell or the Earth, etc."; c) "justify facts or phenomena by using a more or less simple scientific model, such as justifying a change of state using a particles in movement model or justifying the phases of the moon with the Sun/Earth/Moon model". Furthermore, the teachers had to evaluate the importance and difficulty of cognitive-linguistic abilities which involve the expression of certain astronomic statements about daily and annual changes. The statements were the following: a) *"The Sun moves in the sky from east to west throughout the day"* and *"In areas with mild climates there are seasons and the number of daylight hours and the height of Sun varies throughout the year"* (these statements involve the description of facts/phenomena); b) *"The Earth is a spherical shape, it rotates on its own axis"* and *"Earth with its inclined rotation axis revolves around the Sun"* (these statements involve the description of models) and c) "*The sun seemingly moves through the sky during the day because the Earth rotates around itself*" and "*In temperate zones of the planet, both the number of hours of light and darkness and the height of the sun at midday change regularly throughout the year, due to the inclination of the Earth's axis and its movement around the sun*" (these statements involve justification). The summary of statements and codes can be seen in Table 1.

In the analysis of results the following was used: a) the McNemar test in order to detect differences between the maximum evaluation/difficulty granted to the different principles within each group of teachers and b) the Pearson χ^2 in order to identify differences between both groups. The statistics programme SPSS was used (significance value $p<0.05$). An individualized analysis of the evaluations of each teacher was also carried out, independently of the evaluation, in order to see which skill was granted higher importance or level of difficulty (see types of evaluation, Figures 1 and 2).

RESULTS

The majority of the teachers gave the maximum points to the different principles. All of them receive a value 4 or 5 from more than 50% of the teachers (Table 1). Significant differences can be seen between the principles, in particular: a) in the generics, G-FD is more important that G-MD in the Primary group (p=0,001); b) in the daily changes, D-MD taken more into consideration in the Primary group (p=0,031; p=0,022) and more valued that D-FD, in the

Secondary (p=0,049) and c) in the annual changes, A-FD is valued more than A-MD in Primary (p=0,031). When comparing the generic and astronomic principles, it can be seen that in Primary D-MD is more valued than its generic counterpart (G-MD) (p<0,000) and in Secondary the opposite occurs with D-FD (less valued than G-FD) (p=0,04).

Table 1. Teachers who award maximum importance and difficulty (values 4 and 5) to the different principles (generic and astronomy)

Category/Principles		**Importance**		**Difficulty**	
		Prim.	**Secon.**	**Prim.**	**Secon.**
Generics	G-FD Describe phenomena and natural facts	49(1) (83.1%)	45 (83.3%)	23 (39.0%)	13 (24.1%)
	G-MD Describe models or non-observable processes	34 (57.6%)	44 (81.5%)	44(1) (74.6%)	37(1) (68.5%)
	G-J Justify facts and phenomena using a simple model	38 (64.4%)	41 (75.9%)	44(1) (74.6%)	32(1) (59.3%)
Daily changes	D-FD The Sun moves in the sky from east to west throughout the day	43 (72.9%)	32(2) (59.3%)	28(1) (47.5%)	18(1) (33.3%)
	D-MD The Earth is a spherical shape, it rotates on its own axis	53(1)(2) (89.8%)	41(1) (75.9%)	15(2) (25.4%)	6(2) (11.1%)
	D-J The apparent movement of the sun is explained by the Earth's rotation	44 (74.6%)	36 (66.7%)	31(1) (2) (52.5%)	18(1)(2) (33.3%)
Annual changes	A-FD In areas with mild climates there are seasons (nº of hours of light and height of Sun varies)	39(1) (66.1%)	40 (74.1%)	20 (33.9%)	10 (18.5%)
	A-MD The Earth with its inclined rotation axis turns around the Sun.	30 (50.8%)	40 (74.1%)	41(1) (69.5%)	16(2) (29.6%)
	A-J The seasons are due to the inclination of the axis of the Earth and to its passage	32 (54.2%)	36 (66.7%)	39(1) (66.1%)	30(1) (55.6%)

(1) Assessment/consideration of difficulty significantly higher than all or some of the principles of their category (test McNemar; p<0,05)

(2) Assessment/consideration of difficulty significantly differs from its generic counterpart (test McNemar; p<0,05)

The teachers recognize difficulties, detecting the following differences: a) in generic principles, G-MD and G-J are more difficult for both groups (p<0,000); b) in the daily changes, D-MD is more simple for both groups (Primary p=0,004; Secondary p=0,008) and c) in the annual changes, A-MD and A-J in Primary and A-J in Secondary are considered more difficult that A-FD (p=0,002). Moreover, the secondary teachers see more difficulty in the more abstract generic principles (G-MD and G-J) than in their astronomy counterparts (p<0,000) except in the case of AJ. The same happens in the Primary group, but only for daily changes (D-MD p=0,000 and D-J p=0,02).

Using the Pearson χ^2 test, differences are detected between the groups of teachers. The principles G-MD and A-MD are more important for the Secondary group (p=0,006; p=0,01) and D-MD for the primary group(p=0,048). The principles D-J and A-MD are more difficult for the Primary teachers (p=0,04 and p<0,000, respectively).

The comparative analysis of the evaluations of each teacher (Figure 1), shows that for the two groups, type A (the description of facts/phenomena is valued more) is the most frequent in the generic principles. However the frequency decreased in the case of the astronomy principles (daily changes in both groups and annual changes in Secondary). With regards to difficulty (Figure 2), type B (the abstract skills being more difficult) is the most numerous in the generic principles and in the annual changes. However, in terms of the daily changes, more than 40% of the subjects show type A opinions.

Figure 1. Percentage of teachers that: **A** (value FD more than MD and/or J; **B** (value MD more and/or J than FD); **C** value all the principles equally

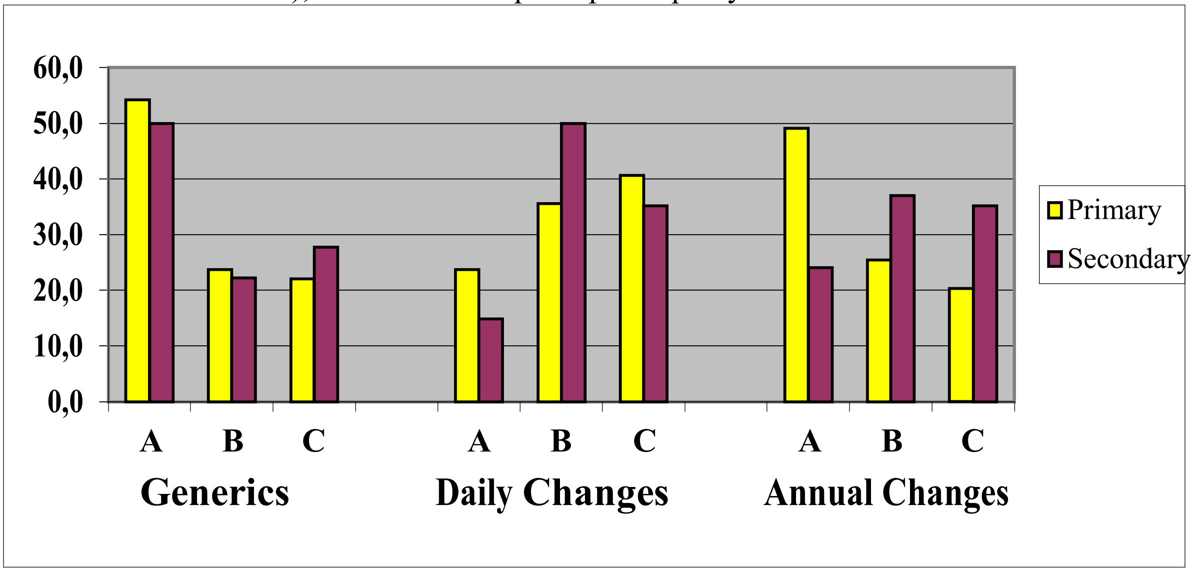

Figure 2. Percentage of teachers that consider: **A** (FD more difficult than MD and/or J); **B** (MD and/or J more difficult than FD); **C** the same level of difficulty in all principles

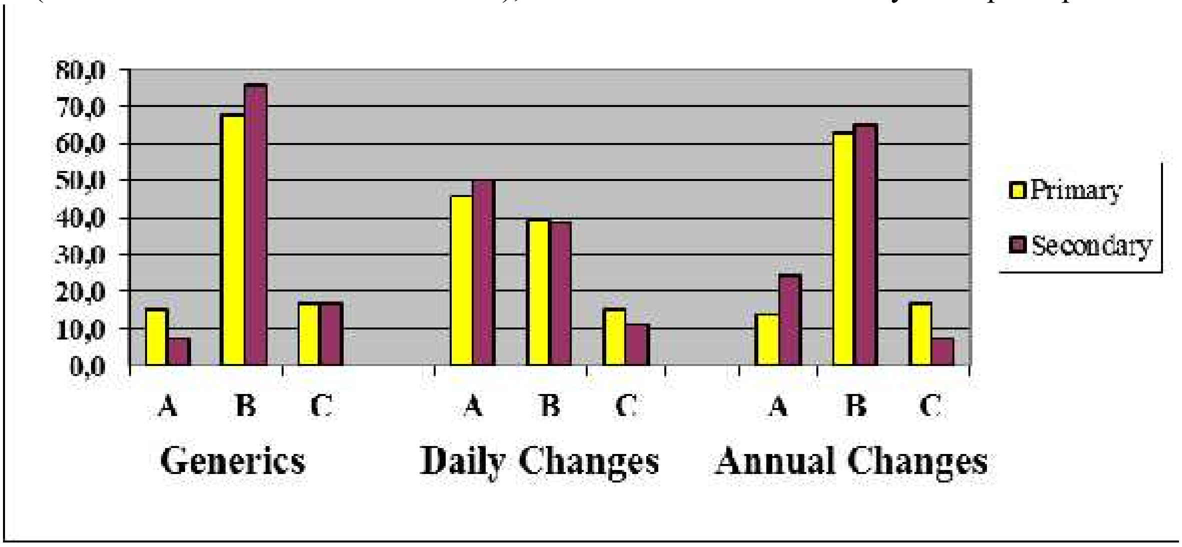

CONCLUSIONS

The teachers positively evaluate the cognitive-linguistic skills, seeing differences in accordance with the content. In general, the description of facts/phenomena is considered more in generic terms and the skills that require more abstraction are valued more in relation with astronomy knowledge.

The teachers attribute more difficulty to generic skills that require more abstraction than their counterparts associated with astronomy aspects.

Few differences are detected between the groups of teachers. They focus on the evaluation of the description of models and on the difficulty attributed to some skills that require more abstraction by the Primary group.

This seems to demonstrate that the teachers do not sufficiently value the observation of astronomy phenomena and that they do not always perceive the difficulty of the use of the model and justifications, at least in the case of the daily changes, despite its complication (Baxter, 1989). We understand that the permanent training should focus on the importance of observation, as it is a key aspect which is going to favour the establishment of questions and open the way to the use of explanatory models and to the justification of the facts observed. To achieve this, a recent study (Navarro, 2011), recognising the importance of the observation of the sky, suggested a teaching proposal based on the resolution of problems and it was successfully developed in a Primary classroom. The ideas of the students evolved satisfactorily.

This study is part of the Project INCITE08XIB106098PR , financed by the Autonomous Government of Galicia (Spain).

SCIENCE TEACHERS' ATTITUDES AND PERCEPCTIONS RELATED TO PRACTICAL WORK: A SELF REPORT QUESTIONNAIRE

M. Teresa Guerra-Ramos[1], José B. García-Horta[2], Dulce López-Valentín[1], Adrianna Gómez-Galindo[1] and Rocío Balderas-Robledo[2]
[1]Science Education Group, Cinvestav Unidad Monterrey, Nuevo León, México
[2]Faculty of Social Work and Human Development, Universidad Autónoma de Nuevo León, México

Abstract: The purpose of this study was to develop a self-report questionnaire, valid and reliable, to explore teachers' attitudes and perceptions related to practical work. We also aimed to apply the questionnaire to a random sample of secondary teachers and provide data contributing to a characterization of teachers' attitudes and perceptions on practical work. Our motivation to conduct this study comes from the renewed emphasis in enquiry based science teaching and practical work in the most recent curriculum reform for secondary science education. The questionnaire, after trialling, pilot studies and consequent refinement, has proven to be a useful research instrument to identify general and individual tendencies. The initial tendencies identified in teachers' responses suggest good predisposition and benevolent attitudes in general; however these contrast with some teachers, reluctance to practical work, lack of confidence and sense of control. We recognize that our questionnaire is useful to explore teacher thinking but it needs to be complemented with other relevant sources of information like ongoing in-depth interviews to explore the challenges and opportunities of using practical work to develop conceptual understanding and process skills. We see this study as a starting point for further research on effective ways of supporting teachers to develop skills and awareness on the potential and limitations of practical work.

Keywords: secondary science teachers; practical work, teacher attitudes; teacher perceptions, questionnaire development.

INTRODUCTION AND BACKGROUNG

Secondary school science teachers usually have to teach a wide and demanding curriculum. The problem of how to support them in initial and in-service training, and to develop the basic knowledge, strategies and skills that they need as practising teachers is still faced by teacher educators around the world. In Mexico, with the recent introduction of a new secondary science curriculum, enquiry based teaching and aspects of the nature of scientific enquiry have a renewed emphasis in the normative pedagogical discourse and associated materials. Teachers are encouraged to incorporate practical work systematically in their practice as in other countries (Anderson, 2007). This places significant demands on the teaching force, given the fairly modest science background of most Mexican secondary school teachers, and the limited opportunities provided to them to be engaged in practical work and investigative processes during their own education and training.

The role of practical work in science education has been widely discussed (Millar et al., 2002; Berg et al., 2003; Lunetta et al., 2007). In this paper, by 'practical work' we mean any teaching and learning activity that engages teachers and students in observing or manipulating concrete objects and materials (Millar, 2004). This term is used in preference to ‘experimental’ or ‘laboratory work’, in order to include those activities involving observation or manipulation conducted in and out of the school setting. Standing from a situated perspective (Brown, Collins and Duguid, 1989), we are aware that many contextual and social elements are involved in complex human interactions such as teaching. Teachers inevitably develop their own perceptions and attitudes towards practical work; those perceptions, in turn, might interact with curriculum demands. Moreover, such attitudes are likely to be reflected in their discourse and actions and may have influence on the activities they provide for students, how they organise and manage their classroom, what role they adopt, the way they use equipment and materials, and the criteria they use in assessing the success of practical work (Abrahams & Saglam, 2010).

As a way to systematically explore secondary science teachers’ perceptions and attitudes related to practical work, we report here the design and development of a questionnaire. The development of the questionnaire was conducted in the context of a larger project oriented to perform a diagnostic study on the use of practical work in science education in public secondary schools in Nuevo Leon, a state in the North-East region of Mexico. Such project also intends to inform the elaboration of teaching materials based on practical work to support the official curriculum. Consequently, our aims were:

- To develop a self-report questionnaire, valid and reliable, to explore teachers’ attitudes and perceptions related to practical work.
- To apply the questionnaire to a random sample of secondary teachers and provide data contributing to a characterization of teachers´ attitudes and perceptions on practical work.

METHODS AND SAMPLES

This paper focuses on their characterization based on a transversal study. We consider the use of a questionnaire only as a mean to gather information and a resource which outcomes should be complemented with data from other sources (e. g. interviews, field notes, classroom observation).

We initially developed a self-report questionnaire containing Likert scale items grouped in sections to explore four aspects:

Section 1: purposes attributed to practical work (20 items)

Section 2: attitudes towards practical work (20 items)

Section 3: perceptions of engagement and control (21)

Section 4: subjective experience during implementation of practical work (36 items)

The following examples illustrate the nature of the items:

Table 1. Examples of items in each section

	Strongly disagree	Somewhat disagree	Neutral	Somewhat agree	Strongly agree
Section 1: Purposes attributed to practical work In science lessons, enquiry and practical activities intend that students...					
	Strongly disagree	Somewhat disagree	Neutral	Somewhat agree	Strongly agree
Learn to use instruments or tools (e. g. a thermometer)					
Collaborate among them and work in groups.					
Section 2: Attitudes towards practical work					
	Strongly disagree	Somewhat disagree	Neutral	Somewhat agree	Strongly agree
When doing practical activities, students ask things I do not know and make me feel uncomfortable.					
Practical activities work well if I prepared them well.					
Section 3: Perceptions of engagement and control					
	Strongly disagree	Somewhat disagree	Neutral	Somewhat agree	Strongly agree
I only conduct the practical activities appearing in textbooks because I have no time to look for other ones.					
I have to conduct practical activities in my science classes, although I don´t like them.					
Section 4: Subjective experience When I conduct enquiry and practical activities I feel...					
	Strongly disagree	Somewhat disagree	Neutral	Somewhat agree	Strongly agree
Organized					
Dominant					
Stressed					

In the development and application of the questionnaire we followed these stages:

I. Pilot study: elaboration of items, revision of items by external judges, initial application to a small intentional sample of teachers, items analysis, integration of the refined version of the questionnaire.

II. Final application: To a random extended sample of teachers, items analysis (validity and reliability tests), response analysis, characterization of attitudes and practices related to practical work.

41 teachers were selected intentionally to participate in the pilot study. 102 teachers comprised the sample for the final application. Both groups of participants included female and male teachers aged 23-56, with 2 to 34 years of teaching experience; all were practicing secondary school science teachers working in state secondary schools. The first version of the questionnaire used in the pilot study included 96 items. The final version, after refinement, ended up with 100 items.

In the pilot study data analysis looked for statistical evidence on the discriminative power and internal consistency of the items, which could tell us about the validity and reliability of the questionnaire as a research instrument. For this purpose, t tests and Cronbach’s Alpha coefficients were performed with SPSS v.14. Data coming from the final application was also processed statistically to confirm the validity and reliability of items, but the main analysis intended to identify patterns and tendencies in teachers´ responses.

RESULTS

The analysis of the pilot study data indicated that 84 of the initial 97 items had adequate discrimination power (t test, $p<0.05$); this indicated the need to refine 13 items. Regarding the internal consistency within each section, we obtained high and significant

Cronbach's alpha coefficients ($p<0.05$) for sections 1(purposes) and 2 (attitudes) with all items being correlated and suggesting good internal consistency. For sections 3 (engagement and control) and 4 (subjective experience), coefficients were no significant and it was possible to identify 19 items with no correlation to their sections. Since both statistical tests pointed out problems with mostly the same items, we proceed to review and refine them. Such review resulted in the eventual restructuration of sections 3 and 4. A second version of the questionnaire was trialled again with a sample of 20 teachers. This time we obtained satisfactory t values for each item and significant alpha coefficients for each section. These results gave us confidence in the use of the questionnaire as a research instrument.

In the final application, we ran the statistical tests for confirmatory purposes and found no significantly different results. Teachers tended to attribute as many cognitive as affective purposes to practical work which suggest that, as a group, they conceive that practical work is useful for almost any teaching purpose. Interestingly, they avoided to totally agree or disagree with items stating that practical work was useful to maintain the discipline in the classroom. 69% of teachers (71 out of 102) reported to hold positive attitudes towards the implementation of practical work. They expressed agreement with negative attitudes only in the case of two items related to the possibility that activities may not work or were likely to cause accidents. Although individually teachers differ significantly in their tendencies, an important number of them (79%) tended to perceive themselves engaged and in control when doing practical work. Similarly, in 71% of teachers the tendency was to report the experience of positive subjective experiences when implementing practical work as part of their teaching.

CONCLUSIONS AND IMPLICATIONS

This study was focused on targeted aspects of teacher's attitudes and perceptions related to practical work. It can only provide a characterisation of the main features and tendencies within the sample or at an individual level. This information is useful in building a diagnostic description of how teachers are equipped to face curriculum demands concerning the implementation of practical work and associated aims. We followed the conventional procedure in the design and managed to develop a valid and reliable questionnaire, which is as a self-report instrument that privileges teachers' points of view. In order to make sense of these views, it would be important to explore them in conjunction with knowledge about teachers training background and conditions in schools for practical work. Other relevant aspects to incorporate in our diagnostic study include ongoing in-depth interviews to a subsample of teachers to explore the challenges and opportunities of using practical work to develop conceptual understanding and process skills. A more qualitative approach, like the dilemma discussions adopted by Hye-Gyoung & Mijung (2010) could be fruitful for such purpose.

The questionnaire, after trialling, pilot studies and consequent refinement, has proven to be a useful research instrument to identify general and individual tendencies. The initial tendencies identified in teachers' responses suggest good predisposition and benevolent attitudes in general; however these contrast with some teachers' lack of confidence and sense of control. Despite the sample size in the final application, we are not in the position to generalise the identified tendencies. Our initial characterisation of teachers` attitudes and perceptions will serve as a starting point for further research on effective ways of supporting teachers to develop skills and awareness on the potential and limitations of practical work. Some efforts should be oriented to develop awareness about distinctive teaching purposes and critical teacher interventions when implementing practical work with secondary school students.

WHAT STRANDS OF RESEARCH IN SECONDARY "NANO-EDUCATION"?

Bénédicte Hingant[1,2,3] *and Virginie Albe*[2]
[1] Laboratoire ICA, Grenoble
[2] Laboratoire STEF, ENS de Cachan
[3] Institut Néel, Grenoble

Abstract: We present a review of literature that gives a snapshot of an emerging field in science education: "nano-education", with a focus on secondary education. Our corpus was maid of 20 articles from science education peer-reviewed journals and conference proceedings. We identified four strands of research: reflections prior to curriculum development on nanosciences and nanotechnologies; studies on students' conceptualisations of nano-related concepts; use of haptic tools to teach nanosciences and nanotechnologies; and professional development for secondary school teachers. We also pointed the lack of research regarding nanosciences and nanotechnologies as a socioscientific issue.

Keywords: Nanotechnologies - Nanosciences - Secondary education - Nanoliteracy - Curriculum development

BACKGROUND, FRAMEWORK AND PURPOSE

Since the launch of the National Nanotechnology Initiative by the US government in 2000, many countries have been investing in nanosciences and nanotechnologies developments. These investments are often accompanied by discourses laying emphasis on the interests to introduce nanosciences and nanotechnologies into the science curriculum (Roco, 2003) and also by funding to develop pedagogical materials as well as educational research on this topic. This is particularly pronounced in the US where the National Science Foundation has made many efforts to introduce nanosciences and nanotechnologies[1] in secondary schools' classrooms and alloted many grants for research on "nano-education". As a result, science education on nanosciences and nanotechnologies has been developing for a few years and this emerging field in science education may undergo important expansion in years to come.

We have worked on reviewing research literature in science education dealing with the introduction of "nanos" in secondary education (Hingant and Albe, 2010). Our purpose here is to give an insight into the directions in which science education research on nanosciences and nanotechnologies has been developing so far and has already produced results.

RATIONALE

Many attempts have already been made to introduce nanosciences and nanotechnologies in secondary education in particular in the US. Accordingly, our aim was to provide an overview of this emerging field by reviewing literature to answer the following questions:

Which orientations of research about the introduction of nanosciences and nanotechnologies in secondary education have started to be explored?

Which results have already been yielded by these studies?

METHODS

The words nanosciences and nanotechnologies refer to a vast collection of scientific and technological research and developments involving nanometric objects. However actors involved in these developments do not agree on what deserve the tag “nano” and what is excluded from nanosciences and nanotechnologies. For our review, we left it to the authors to chose their own definitions of “nanos” and we only used articles whose authors claimed an interest for introducing nanosciences and nanotechnologies in secondary education. Accordingly, we chose the key words “nanoscience(s)”, “nanotechnology(ies)” and “nanoscale” along with “teaching” and “education” when searching articles. We gathered papers using ERIC database and reviewing papers from various English, French and US peer reviewed journals: *Science Education, International Journal of Science Education, Journal of Research in Science Teaching, Aster, Didaskalia, Journal of Science Education and Technology, Research in Science Education, International Journal of Science and Mathematics Education, American Educational Research Journal, Review of Educational Research, Educational Evaluation and Policy Analysis, Review of Research in Education, Journal of Curriculum Studies, Studies in Science Education.* We also visited selected Internet websites that led us to consult different conference proceedings (of the National Association for Research in Science Teaching conference and of the American Society for Engineering Education) as well as the *Journal of Nano Education* created in March 2009. We retained 20 documents, excluding from our corpus papers only depicting an innovation and lacking a sound theoretical framework.

RESULTS

We identified four orientations of research. The first one is related to reflections prior to the design and implementation of a “nano-curriculum”. Studies have also been completed on the conceptualisation of some “nano-related” concepts. Some work deal with the use of some particular learning tools to teach students some nano-related concepts. We also encountered articles that were dealing with secondary school teachers' professional development on nanosciences and nanotechnologies.

Reflections prior to the design and implementation of a “nano-curricula”

Among the questions preceding the design and implementation of nano-lessons we listed the following:

- Why to introduce “nanos” in secondary education and who is targeted?
- How to organise teaching nanosciences and nanotechnologies in secondary education?
- What concepts are considered prominent to understand the heterogeneous objects grouped together by the words nanosciences and nanotechnologies and how can these concepts be integrated in the science curriculum?

We identified two reported goals put forward to advocate the introduction of nanosciences and nanotechnologies in secondary education:

- To recruit the future “nano-workforce”;
- To provide citizens-in-the-making with tools to understand a world pervaded with nanotechnologies.

To introduce nano-contents, Schank, Krajcik, & Yunker, (2007) and Stevens et al., (2009b) emphasise the inherent interdisciplinarity of nanosciences and nanotechnologies. Stevens et al., (2009b) also underline the significance to take into account the existing constraints set by the educational systems. For their part, Schank et al. (2007) go further and consider that nanosciences and nanotechnologies provide an opportunity to profoundly reform the way science is taught in secondary education.

Finally concerning the concepts to be taught and deemed central to understand nanosciences and nanotechnologies, the National Science Foundation funded workshops in 2006 and 2007 gathering educators and scientists to identify “big ideas” of nanosciences and nanotechnologies. This resulted in the identification of nine big ideas and their associated learning goals appropriate for secondary education (Stevens et al., 2009b):

1.Size and Scale
2. Structure of Matter
3. Force and Interactions
4. Quantum Effects
5. Size-Dependent Properties
6. Self-Assembly
7. Tools and Instrumentation
8. Models and Simulations
9. Science, Technology and Society.

Works on conceptualisation of “nano” related concepts

Significant concepts to understand nanosciences have been targeted for example in the book “the big ideas of nanoscale science and engineering” (Stevens et al., 2009b) and empirical works have been completed on the conceptualisation of these notions:

- *on size and scale*: some works tend to show that people and in particular pupils encounter difficulties in apprehending small scales (Tretter, Jones, Andre, Negishi, & Minogue, 2006a; Tretter, Jones, & Minogue, 2006b). Tretter *et al.* (2006b) have also laid emphasis on the significance of direct experiences to conceptualise scales. Other authors have tried to understand how students develop their conceptions of size and scale and plan to use their findings to develop a learning progression on size and scale (Delgado, Stevens, Shin, Yunker,& Krajcik, 2007). They found that students' knowledge ranged from connected to entirely disconnected.

- *on the “nature of matter”*: having identified crucial concepts for the understanding of two constructs, atomic model and electrical forces, Stevens, Delgado, & Krajcik (2009a) have sought to develop two hypothetical learning progressions and striven to enhance the links between them. Their empirical study showed that students often did not perceive connections important to conceptual understanding.

- *on size dependent properties*: in an exploratory study, Taylor & Jones (2009) found there is a correlation between proportional reasoning ability and understanding surface area to volume relationships.

Works on the use of innovative tools to teach nano-related concepts

Innovative learning tools have been used to teach nano-related concepts. In particular, some devices consisting in a haptic[2] interface coupled to an Atomic Force Microscope have been studied. The influence of haptic on learning and motivation has been investigated (Jones et al., 2004; Jones, Andre, Superfine, & Taylor, 2003). Results showed that using such devices has a positive impact on both students learning and engagement (Jones et al., 2004; Jones et al., 2003). In addition, results obtained by Jones et al. (2006) tend to indicate that the more sensitive the haptic tool is, the more efficient it proves in engaging students in activities and in supporting learning.

Studies on teachers’ professional development

If nanosciences and nanotechnologies are to be integrated in the science curriculum, teachers have sooner or later to be in charge of the teaching of these new contents. Consequently some works are taking an interest in secondary teachers' professional development. Some authors have described the hurdles which may dissuade teachers from integrating "nanos" into their lessons: difficulties to take into account interdisciplinarity, reluctance to deal with notions they have not been acquainted with during their initial training and on which they may be at a loss to answer pupils' questions (Schank et al., 2007). However, a few professional developments opportunities on nanosciences and nanotechnologies have already been offered to secondary school teachers and some have been studied in empirical works.

Tomasik et al. (2009) found that the learning environment used for their course met teachers expectancies and that teachers chose to introduce nano-lessons throughout the year or as one bulk unit.

Bryan et al. (2007) noted that teachers came to a nano-summerschool program mainly to learn nano contents and not about inquiry.

Concerning teacher's use of models for teaching nanotechnologies, it has been found that teachers view them as primarily useful for "show and tell" purposes (Bryan et al., 2007; Daly and Bryan, 2007)

Finally, Bryan et al. (2007), Daly et al. (2007), and Hutchinson et al. (2009) reported some difficulties encountered by teachers to implement nanosciences and nanotechnologies contents in their classrooms. Teachers have to locate where it could fit. Bryan et al. (2007), Daly et al. (2007), and Hutchinson et al. (2009) found that "nanos" were often added as extensions to pre-existing lessons. Hutchinson et al (2009) also pointed out that teachers could lack time and confidence and also encounter technical difficulties to teach nano-lessons. Daly et al. (2007) and Hutchinson et al (2009) also underlined that teachers sometimes had difficulties to cope with interdisciplinarity.

CONCLUSIONS AND IMPLICATIONS

Our literature review provided four strands of research: reflections prior to the introduction of nano-lessons in the curriculum; studies on students' conceptualisations of nano-related concepts; use of innovative learning tools to teach nano-related concepts; and professional development for secondary school teachers. Thus, in the articles we vetted, we haven't found any studies regarding nanosciences and nanotechnologies as a socioscientific issue. However these developments raise controversies and among the "big ideas" deemed essential to grasp an understanding of nanoscale science and engineering the item "science, technology and society" was included (Stevens et al., 2009b). Consequently, to us, if nanosciences and nanotechnologies are to be introduced in secondary education so that every student could understand and participate in the debates surrounding these developments, the controversial dimensions of nanotechnologies also have to enter the classrooms.

NOTES

1. In the United States, authors working on the introduction of nanosciences and nanotechnologies in secondary education often use the terminology "nanoscale science and engineering" (e.g.: Stevens, Sutherland, and Krajcik, 2009b).

2. A haptic tool is a tool rendering the sense of touch.

SOURCES OF SCIENCE TEACHING SELF EFFICACY BELIEFS OF EXPERIENCED HIGH SCHOOL SCIENCE TEACHERS

Zeynep Tugba Kahyaoglu[1]
[1]Middle East Technical University

Abstract: This ethnographic research aims to search for the sources of self-efficacy beliefs of experienced high school science teachers. Semi-structured formal interviews were made with three experienced science teachers (one biology, one chemistry and one physics teacher) who had experience over nine years of teaching. Results revealed that teachers' problem solving, teachers' making experiments and students' interest during lesson are sources of an increase in experienced science teachers' teaching science self efficacy beliefs. Outer factors related with students and class atmosphere are sources of a decrease in science teachers' teaching science self efficacy beliefs. Science teachers' mastery experiences especially the indirect, perlocutionary mastery experiences which include students' success and interest was found to be most highlighted source of teachers' science teaching self efficacy beliefs. Social/verbal persuasion is reported as a second effective source. Vicarious experiences and psychological and emotional arousal was mentioned by science teachers as not much effective for their teaching self efficacy beliefs. This study suggests that the great effect of mastery experiences on science teachers self efficacy beliefs would be analyzed deeply and might be separated into components and specific teaching activities for science teachers should be analyzed with respect to their effects on science teachers' more static and developed science teaching self efficacy beliefs.

Keywords: science teaching self efficacy beliefs, sources of self efficacy, experienced teachers, high school science.

BACKGROUND, FRAMEWORK, AND PURPOSE

Bandura (1986, p. 391) defined self-efficacy beliefs as "People's judgments of their capabilities to organize and execute courses of action required to attain designated types of performances". A teacher's self efficacy belief is so crucial because literature supports its consistent positive relationship with teacher behavior and student outcomes (Gibson & Dembo, 1984). Moreover, Ashton (1984) stated that "…no other teacher characteristic has demonstrated such a consistent relationship to student achievement" (p. 28).

A teacher's sense of efficacy may influence their emotive state, their goal setting and their persistence (Ashton and Webb, 1986). Denham and Michael(1981) found that there is some evidence to suggest that teacher attitudes influence teacher behaviours and that teacher behaviours influence student achievement. Research that is more recent has found that teacher self-efficacy beliefs strongly influence the nature of a teacher's role, planning, and, consequently, curriculum and student learning (Tobin, Tippins, and Gallard 1994). For, example, in science teaching, teachers with high self-efficacies were found to be more likely to use inquiry and student-centered teaching methods, while those with low self-efficacies were more likely to be teacher directed (Czerniak, 1990).

Research on science teachers' self efficacy beliefs is one of the growing trends among teacher education researchers recently. Science teaching efficacy is defined as a teacher's belief about his/her capability to teach science effectively and to affect student achievement

(Riggs, 1988). Science teaching efficacy belief has two dimensions in accordance with the Bandura's two sub-constructs within the conceptualization of self efficacy: personal science teaching efficacy beliefs (PSTE) and science teaching outcome expectancy beliefs (STOE). PSTE refers to a teacher's belief in his/her ability to perform required science teaching behaviors and STOE refers to the teachers' beliefs about the statement of "students can learn science given external factors such as their family background, socioeconomic status (SES), or school conditions" (Riggs, 1988, p. 20). As Bandura asserted, one's self efficacy is task or role specific and it can be changed according to situations. Therefore, teachers' self efficacy is examined under their subject area and its changing is examined for different conditions of teachers, that is, generally for pre-service and in-service conditions.

The usefulness of a high level self efficacy of teachers is obvious. However, the vital question here is "what are the sources of self efficacy?" Bandura (1997) defines four sources of efficacy building information: mastery experiences, vicarious experiences, social/verbal persuasion and psychological and emotional arousal. Determining specifically the sources of teachers' self efficacy in their subject area teaching would be helpful for teacher training or assisting teachers in schools and for developing self efficacy scales for science teachers.

This study aims to answer three main questions revolving around sources of experienced science teachers' self efficacy beliefs. These are:

1. What types of experiences are considered by experienced science teachers as effective for increasing their science teaching self efficacy beliefs?
2. What types of experiences are considered by experienced science teachers as effective for decreasing their science teaching self efficacy beliefs?
3. How are experienced science teachers' self efficacy beliefs linked to Bandura's four sources of self efficacy beliefs?

RATIONALE

Dembo and Gibson (1985) stated that "The problem of identifying antecedents of efficacy and developing ways to enhance teachers' sense of efficacy is critical…researchers must consider many variables as well as the complex manner in which they interact" (p.177). There is a great mount of researches about self efficacy of pre service teachers. Self efficacy of in service teachers is a less searched area than of pre service teachers. In fact, a more developed, and more static self efficacy of experienced teachers is need to be searched in order to understand what pre service teachers are going to face with in their following years and also as Ramey-Gassert, Shroyer and Staver (1996) stated, to understand how to motivate teachers to teach science.

Based on the theoretical implications and literature evidence of positive effects of self efficacy in affecting teacher behavior, this ethnographic research aims to search for the sources of self-efficacy beliefs of experienced high school science teachers. In the literature studies about elementary school science teachers' self efficacy beliefs are dominant and hence studies for high school science teachers' science teaching self efficacy beliefs is a bigger gap today. Determining specifically the sources of high school science teachers' science teaching self efficacy beliefs would be helpful for teacher training and assisting science teachers in high schools and for developing self efficacy scales for high school science teachers.

METHODS

Semi-structured formal interviews were made with three experienced science teachers (one biology, one chemistry and one physics teacher). Three science teachers who were female and had experience over nine years of teaching were chosen purposively. Interviews were recorded by audiotape and transcribed in documents. At the beginning of the interviews, an introduction and basic interview guidelines were presented to the teachers. To provide clearness of the terms “self efficacy” and “teaching self efficacy” for teachers during the interview, the explanation of the terms in Turkish, which are provided by academic studies, were both given the teachers in a written paper and explained by the researcher orally. Also, researcher asked to the teachers whether they understood them. Interviews began after researcher was convinced that teachers grasped the terms. Teachers were told that they were going to be asked a series of questions related with teaching self efficacy.

The questions of the interview are prepared by examining the self efficacy tests in the literature. Some items in the tests are turned into question form. There are three parts in the interview. After getting the general information about teachers in the first part, questions about vocational thoughts were asked in the second part. Then for the final part, questions about “how efficacy is influenced and what influences efficacy” were asked. Two listed item questions were asked. These two questions were developed by taking views and answers of other three experienced teachers to the question of “what makes you feel more efficacious in teaching?” The defined items are listed and asked to interviewees to give points from 1 to 5, to show its impact on that feeling of teaching self efficacy.

Finally, the data were grouped and analyzed with clustering technique (Miles & Huberman, 1984) with respect to answering the two main questions of the research.

RESULTS

Results are presented under headings of the three main questions of the study. But before seeing separate and somewhat different views of the teachers, it would be meaningful to give their some personal characteristics.

Profiles of Teachers

Biology teacher: She was 30 years old. She had 9 full years of teaching experience and a master degree in biology. She had taught in university entrance examination preparation courses for 7 years and then she had been teaching in a private school for two years. She said that she had had a great interest in biology and so chose to be a biology teacher. She defined herself as curious and effortful towards science and hence loved her job; teaching. It is noticeable that biology teacher linked the attitude towards science and loving to teach. She answered as “yes” when interviewer asked her whether she saw herself as a successful teacher and she immediately continued by adding “it isn’t a self conceit, right?” In Turkish culture it is commonly accepted as discreditable for someone to praise herself/himself and this biology teacher was so certain about her goodness in teaching such that she worried to assert this explicitly.

The strengths and weaknesses in teaching profession were asked to teachers. Biology teacher said that due to long time she had spent in university entrance preparation courses she was good at those subjects asked in UEE (university entrance examination) and making students study –in UEE courses students are scheduled to study and solve necessary number of tests about exam subject and they are controlled by teachers periodically. Hence, an important role of teachers in those courses is to make students study and to control their plan, in other words, to help students self regulate studying-. She explained her vocational weaknesses as making experiments, fieldtrips and observation. Moreover she explained that those weaknesses were due to her insufficient experience in school teaching and she added that she needed development in those school activities.

Chemistry teacher: She was 35 years old. She had 14 full years of teaching experience and in last two years of her teaching she was also an administrative staff in her school. She said that the reason of her choice to be a chemistry teacher was that she had loved her chemistry teacher much in high school. She defined herself as “not a very good teacher but a little above the middling good teachers”. When interviewer asked her whether she saw herself as a successful teacher she said “not much, I think”.

Chemistry teacher criticized herself about not spending much time on her professional development and mentioned it as a weakness in her profession. She explained her weakness such that she would have solved much more chemistry problems and would have finished various test books and she would have made experiments alone in laboratory. She mentioned her good lecturing as strength in her teaching profession.

Physics teacher: She was 37 years old and had 16 full years of teaching experience in high schools. She stated her reason of choice to be a physics teacher as her bad physics teacher in high school. The interviewer conceived that this choice was a reaction to interviewee’s suffering in her studentship and hence she had wanted to show a better performance in physics teaching than her bad teacher had shown in the past. She defined herself as a teacher who was trying to have close relationship with her students emotionally and trying to understand them. Moreover she explained the principle of her behavior by saying “in order for students to love the lesson they must first love the teacher”.

When interviewer asked her whether she saw herself as a successful teacher she said that her success depends on classes. In Turkey, in most schools, classes are formed by ability grouping and so meaning of classes in her explanation is success levels of students. She also explained classes’ effect by saying that in good classes her success was better and in bad classes she was trying to help students as much as possible. Physics teacher asserted her deficiencies in classroom management as a weakness and asserted her good subject matter knowledge as strength in her profession.

Increase in science teaching self efficacy beliefs

According to biology teacher solving many problems about subjects increases her science teaching self efficacy beliefs mostly. Chemistry teacher also supported this by exemplifying as skimming and solving problems in different test books. Physics teacher did not say something explicitly about the effect of solving problems on her self efficacy beliefs, however when the instructional activities were asked to put in an order from most to least affective on her teaching self efficacy she put solving problems in the second place.

The other thing that all three science teachers mentioned about its effect on their teaching self efficacy is the interest that students exhibit to the lesson. Biology teacher gave examples of signs that indicate students’ interest for the lesson: students’ listening to lesson carefully, their participation by asking questions and problems that they could not solve, their note taking, their smiling when teacher changes her tone of voice and students’ oral statements about their grasp.

All three teachers supported that making experiments would affect their teaching self efficacy. What is more all of them put *making experiments* on the first place among instructional activities that affect teachers’ science teaching self efficacy. It is worthy that all three science teachers put the instructional activities in the same order with respect to their effects on their science teaching self efficacy. The order was like that: 1. *Making experiments*, 2. *Solving problems*, 3. *Answering questions that students ask*, 4. *Concept Instruction*.

The first research question of the study was that “what types of experiences are considered by experienced science teachers as effective for increasing their science teaching self efficacy beliefs? Results of this study provide an answer for this question like that: teachers’ problem solving, teachers’ making experiments and students’ interest during lesson are sources of an increase in experienced science teachers’ teaching science self efficacy beliefs.

Decrease in science teaching self efficacy beliefs

The reverse of the things that teachers told as increasing their teaching self efficacy is also valid for decreasing it obviously. However, in this section the things that teachers especially mentioned about their negative effect on their teaching self efficacy beliefs are written.

The things that would affect teaching self efficacy negatively for biology teacher were getting a poor score from the examination for teachers –in the private school she worked there were teacher exams for all branches each year-, not getting feedback from students during instruction, not solving more tests and problems and a consensus occurred in the class about not understanding the subject. For chemistry teacher the naughty students who did not progress positively after help, not spending enough time on her professional development-by making experiments in the laboratory- were the things that would increase her teaching self efficacy. According to physics teacher students’ being uninterested, unwilling and not having enough previous knowledge for the subjects would increase her teaching self efficacy beliefs.

The second research question of the study was that “what types of experiences are considered by experienced science teachers as effective for decreasing their science teaching self efficacy beliefs?” The gathered answer for this question from the study is that a consensus occurred in the class about not understanding the subject, uninterested and unwilling students, students not having enough previous knowledge for learning new subjects, problematic students who did not progress after help and bad class atmosphere are sources of a decrease in science teachers’ teaching science self efficacy beliefs.

Links to Bandura’s four sources of self efficacy beliefs

The third and last research question of the study was that “how are experienced science teachers’ self efficacy beliefs linked to Bandura’s four sources of self efficacy beliefs?” Gathered results are summarized according to their links to four sources of self efficacy (mastery experiences, vicarious experiences, social/verbal persuasion and psychological and emotional arousal) that are defined by Bandura (1997).

Mastery experiences are mentioned to be most effective by science teachers for their self efficacy beliefs, and this is consistent with what Bandura asserted about effect of mastery experiences on self efficacy beliefs (1997). Getting a high score in teachers’ examination, solving problems and making experiments are mastery experiences that teachers explained that they affect their teaching self efficacy beliefs. However teachers gave more explanations about the effect of students’ achievement, interest and participation to the lesson on their teaching self efficacy beliefs. Moreover, although it is obvious that mastery experience of teaching the subject for years is one of the major source of teaching self efficacy of teachers however, it is not mentioned by teachers in this study maybe due to they are all experienced teachers and do not have concerns about their enduring teaching skills.

Teachers especially mentioned that verbal persuasions are not much affective whereas social persuasions such as students' consensus on teacher effectiveness will be very effective on their teaching self efficacy beliefs. According to teachers, students' empty compliments will not be affective but their sincere views and statements about learning by instruction of teacher will be affective. Verbal persuasions of administrative staff and other teachers are mentioned as weakly affective for their teaching self efficacy beliefs.

The least affective source of teaching self efficacy beliefs for science teachers was vicarious experiences. All three teachers asserted that they seldom compare their selves with other teachers. According to chemistry teacher and physics teacher this would happen only when they see or hear that other teachers use a new instructional tool or strategy effectively. In that case, teachers indicated that they would try to learn and apply the new thing that other teachers do. Biology teacher said that enthusiasm of another teacher might affect her teaching performance positively.

Psychological and emotional arousal does not seem to be affective for science teachers self efficacy beliefs. Only physics teacher said that sometimes negative events she faced in her daily personal life would decrease her teaching self efficacy beliefs. But, she highlighted that she was trying to eliminate the positive effects of those personal life events and succeeded at that at ninety percent.

Other source of teaching self efficacy beliefs of science teachers would be outer conditions which are generally temporary and under not control of teachers. For example, physics teacher and chemistry indicated that students' previous knowledge that are necessary for learning new subject is very important for themselves to feel their selves efficacious on teaching this new subject. Physics teacher also pointed out that class atmosphere is very important, that is when class' academic level is high she feels herself more successful or vice versa. Biology teacher talked about class atmosphere too. Lastly all three science teachers mentioned about the difficulty of the subject matter as affective on their teaching self efficacy. Some topics in their branches are more difficult than others and they feel less efficacious on teaching these difficult topics due to concerns about students' understanding.

CONCLUSIONS AND IMPLICATIONS

Mastery experiences were mentioned to be most effective by science teachers for their self efficacy beliefs however; mastery experiences might be separated as personal and perlocutionary mastery experiences for teachers. Perlocutionary means "an act of speaking or writing which has an action as its aim but which in itself does not effect or constitute the action, for example persuading or convincing" (seslisozluk). Getting a high score in teachers' examination, solving problems and making experiments are teachers' personal mastery experiences that affect their teaching self efficacy beliefs. On the other hand students' achievement, their interest and participation to the lesson are teachers' perlocutionary mastery experiences that affect their teaching self efficacy beliefs. In fact perlocutionary mastery experiences of teachers might be more important for teachers self efficacy beliefs than their personal mastery experiences since three teachers in that study gave fifty percent and above weight for their effect on students' success when it was asked. Students' reactions and success are important indicators of teachers' teaching success, i.e. mastery experiences.

Social/verbal persuasion effect on teaching self efficacy of science teachers can be divided as social persuasion and verbal persuasion because teachers especially mentioned that verbal persuasions were not much effective whereas social persuasions such as students' consensus on teacher effectiveness would be very effective on their teaching self efficacy beliefs.

In brief, the great effect of mastery experiences -both revealed in the results of this study and in the literature- on science teachers self efficacy beliefs would be analyzed deeply and might be separated into components such as personal mastery and perlocutionary mastery experiences and specific teaching activities for science teachers should be analyzed with respect to their probable and plausible effects on science teachers' more static and developed science teaching self efficacy beliefs.

THE COMPLEX ROAD TO MATHEMATIZATION IN PHYSICS INSTRUCTION

Ricardo Karam[1,2], *Maurício Pietrocola*[1] *and Gesche Pospiech*[2]
[1]School of Education, University of São Paulo, Brazil
[2]Physics Department, Technische Universität Dresden, Germany

Abstract: How to facilitate students' understanding of science's abstract concepts is definitely a major concern of every dedicated physics teacher. However, discussions about promising ways to be successful at this task are not always part of teacher training curricula. With the goal of contributing to the research in this field, we have analysed a set of lectures given by a distinguished physics professor. In this proposal we present the analysis of two lectures where the abstract concepts of charge density and electric flux are taught. The complexity of the mathematization of these concepts is evident both by the considerable amount of time dedicated to it and by the different strategies used by the professor in his exposition. These strategies are described and exemplified. Using the software *videograph* for the video analysis, we were able to identify the specific instants where each strategy takes place as well as their duration and interplay. This dynamical process is visualised with the aid of a timeline generated by the program. In general, our analysis evidenced that the professor adopted a "concrete to abstract" approach, made an extensive use of visual representations and concrete analogies, mentioned idealizations explicitly and made punctual metacognitive remarks. Taking into account the future perspectives of our research, the categorization of the didactical strategies used by this professor shall allows us to develop comparative studies with other lectures on the same topic. Moreover, the derivation promising strategies to teach the structural role of mathematics in teacher training courses is also aimed at by this research.

Keywords: Mathematics in physics instruction, video analysis, mathematization complexity, structural skills.

INTRODUCTION

Physics and mathematics are deeply interrelated since the very origin of scientific knowledge and this mutual influence has played an essential role on both their developments (Bochner, 1981; Gingras, 2001, amongst many others). Mathematical concepts being motivated by physical problems can be found, for instance, at the origin of calculus and its relation to the study of movement or at the development of vector analysis and the need for a mathematization of electromagnetic phenomena. From the physics perspective, mathematical concepts created in an "abstract world" are commonly "applied" by physicists to build their theoretical explanations. The use of conic sections in Kepler's astronomy or of complex numbers in Fresnel's optics are some among many other examples. More recently, this mutual interplay has reached a higher level where the very physical concepts "cannot be divided into a mathematical part and a non-mathematical one" (Boniolo & Budinich, 2005, p. 86).

But what are the implications of this successful relationship for physics education? Despite the significant amount of research on how to improve students' conceptual understanding of physics, works focusing on building a meaningful comprehension of the role of mathematics in physics education are considerably less common. Hestenes (2003, p. 104) raises attention to this fact when he states that "the challenge is to seriously consider the design and use of mathematics as an important subject for physics education research".

A quite widespread view regarding this theme is that mathematical skills are prerequisites for learning physics. However, it seems that the domain of these skills is far from being a guarantee of success (Hudson & McIntire, 1977). Previous research about students' use of mathematics to solve physics problems (Tuminaro & Redish, 2007) has already shown that rote application of formulas without physical reasoning is a rather common strategy. It has also been demonstrated that students face a huge difficulty when they need to transfer knowledge between mathematics and physics (Basson, 2002). It is fairly reasonable to expect that this difficulty is related to instruction methods, but works approaching this field from a teaching perspective are even less frequent.

With the goal of contributing to close this gap, our research is concentrated on the analysis of mathematical reasoning in physics lectures. The ability to use mathematics in physics is divided between *technical skills* - the ones related to the domain of basic rules of mathematics and normally developed in math's classes - and *structural skills* - which are related to the capacity of recognizing the structural role of mathematics in physical thought [1]. Among the latter, the extreme complexity of *mathematization* - translation between the physical world and mathematics - and the main role it played in the lectures from our data demanded a deeper analysis. Even though fostering students' understanding of science's abstract concepts is a major concern of every dedicated physics teacher, promising ways to be successful at this task are not always available. Therefore, in this work we address the following questions: Which strategies are used by an experienced professor to teach the mathematization of the physical concepts of charge density and electric flux? How does the interplay between these strategies take place during the lectures?

METHODS

Aiming at a deeper investigation of the mathematical reasoning in physics instruction, we decided to conduct a case-study at university level. We chose to analyze the lectures of a particular professor from the University of São Paulo for he is widely acknowledged as an excellent lecturer, since he constantly encourages his students to reason about the physical meaning of the mathematical formalism. In this sense, we started from the hypothesis that his approach would focus on the structural role of mathematics instead of its technical aspect.

Our data consist of the recordings of 40 lectures (total of approximately 60 hours of video) from a course on Electromagnetism. Initially, we watched the lectures directing our attention to the moments where mathematical reasoning took part in the exposition. More specifically, we concentrated both on the explanation of fundamental concepts that are expressed mathematically (e.g. each one of Maxwell's equations) and on problem solving moments.

Afterwards, we chose some lectures for deeper analysis with respect to the identified *structural skills.* For video analysis we used the software *videograph*, divided the lectures in 20-second intervals and categorized each of them. In this work, we present the analysis of two lectures in which the structural skill *mathematizing* plays the central role. The content is the introduction of the rather abstract concepts of charge density and electric flux. The complexity of this process is highlighted by the description of different strategies used by the professor and by the image of a timeline where their frequency and interplay can be evidenced.

RESULTS

The following table presents the set of categories that appear more often in the analysis of the two lectures presented in this work. The main goal of both lectures is to *mathematize* the concepts of charge density and electric flux.

Category	Description	Examples from the lectures
Mathematizing M3 Just/Comp. M2 Math Struct. M1 Modeling	The process of mathematization occurs in a gradual way. Initially, the professor makes an extensive use of concrete representations and clarifies the idealizations imposed by the theoretical model. Then, mathematical structures are used to represent physical quantities and their relations. Normally, justifications for the use of certain structures and comparisons between different mathematical representations are presented and discussed.	*"This page is not bi-dimensional, but I think of it as if it were" M1* *"We normally use Cartesian or polar coordinates to think about the two-dimensional situations" M2* *"We use polar coordinates because the situation is symmetric" M3*
Visual representations V2 Pictorial V1 Gestural	Along the process of constructing mathematical representations of the physical concepts of charge density and electric flux, the professor makes use of several visual representations. More specifically, many drawings are made and his language is extremely gestural.	*"This is theta* (points at the door) *this is theta plus d theta* (opens the door)*" V1*
Analogy A2 Formal A1 Material	Analogical reasoning is extensively used during the lectures. Everyday life examples and material analogies with other physical phenomena have a powerful role in the construction of the physical concepts of charge density and electric flux. Moreover, catching attention to formal similarities is also a common strategy.	*"How can we describe the population density of our country?" A1* *"They took this mathematical formulation to use in many other cases [...] But there are important differences" A2*
Metacognition	Metacognition is the knowledge and awareness of one's own cognitive processes and the ability to monitor, regulate and evaluate one's thinking. The professor frequently encourages his students to think about their own thinking during the lectures.	*"His question is very good. It indicates confusion, but this always occurs with everyone who studies this thing. If it did not occur with you, it's because you didn't realize it yet"*

Table 1: Description of the most common strategies used by the professor to mathematize the physical concepts of charge density and electric flux with examples from the two analysed lectures.

Charge density lecture

The following timeline (Fig. 1) - created with the software *videograph* - is a visual representation of a lecture on charge density. It provides an insight to the dynamics of the explanation process that took place during the lecture.

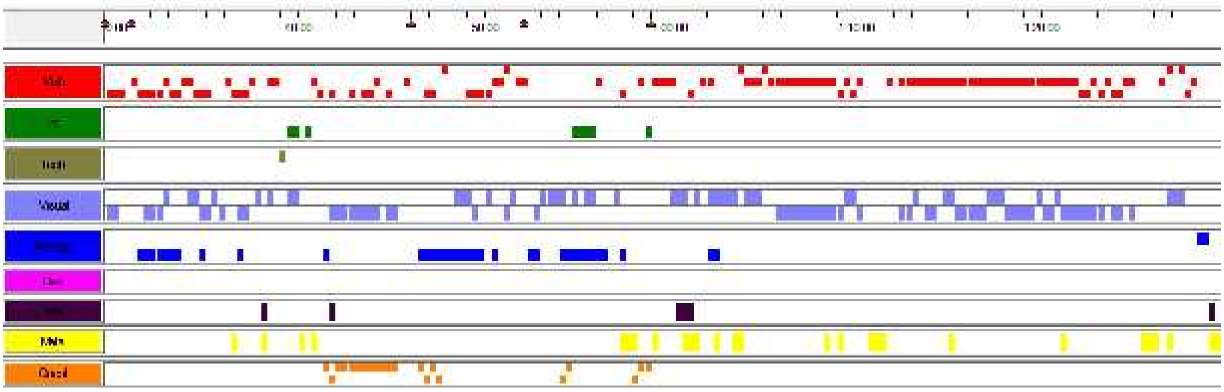

Figure 1: Timeline containing 60 minutes of the charge density lecture. Description of the categories from bottom to top: Quest - Dialogues between the professor and the students; Meta - Metacognitive remarks. Phi - Philosophical comments; Ded - Mention to deductive aspects; Analogy - Everyday life examples, material analogies with other physical concepts and formal similarities between different physical phenomena; Visual representations – gestural and pictorial; Tech - technical manipulations; Int - Interpreting mathematical expressions physically; Math - Translation between the physical world and mathematics.

This timeline allows us to identify the importance of each strategy used by the professor as well as the time dedicated to them. It is clear that visual representations (light blue) play an important role to make the abstract idea of charge density more intelligible. An intensive use of gestures is detected, for example, when the professor explains three different coordinate systems to describe volumetric charge density with the aid of a box and the classroom door. Several pictorial representations, as well as concrete analogies (dark blue), are employed as sources of explanation for the introduction of each different case of charge density (linear, surface and volume).

It is also possible to notice that the idealization process and the use of mathematical structures are highly important due to the time dedicated to them (red). By watching the lecture, one realizes that the professor makes an effort to mention them explicitly. The frequent shift from concrete representations to idealizations is also noticeable and metacognitive remarks (yellow) are frequent along the whole lecture. In the end, a longer moment of justification takes place as if the reasons why the students should learn the mathematical description of charge density are being summarized.

The following transcripts from the professor's discourse and their corresponding categorization complement the described analysis:

32:00	Imagine that you are all point charges and I want to calculate the net field at the position where I am. (A1, V1)
1:00:20	This (reference of frame) is a reasoning instrument, it is not in nature, but in your mind. It is an invention. (Met, Phi)
1:09:20	That is actually not a square, but if everything is very small, then it is useful to make this approximation. (M1, V2)
1:29:00	Today we learned some strategies to deal with distributions of things. This is very general, it can be with charge, mass, population, anything that needs to be distributed. Cosmology, stars, galaxies, Parsec, all [...] This makes sense and this is the way we think. (A2, Met)

Electric flux lecture

In the analysis of the electric flux lecture, we notice a similar pattern, which is illustrated by the timeline presented at figure 2.

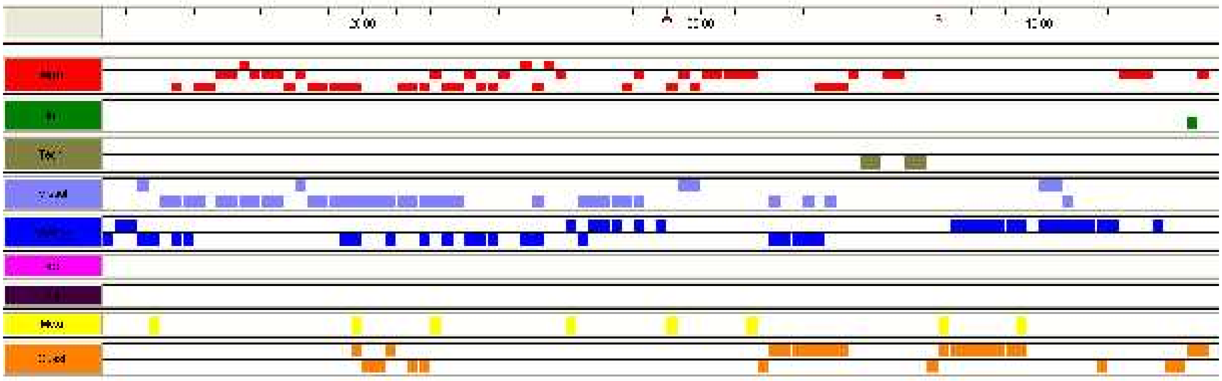

Figure 2: Timeline containing 32 minutes of the electric flux lecture.

The professor starts this lecture with different physical phenomena where the notion of flux applies, mentioning everyday life examples and using several analogies. Then, each relevant variable that influences this magnitude is mentioned and discussed with the students. Once again, we notice that visual representations (especially gestures) are extremely useful for the explanation of the concept.

Instead of just giving the mathematical formula of the flux of a vector field through a surface, the professor presents its mathematical structures (dot product and surface integral) as reasonable for the description of the flux concept. Moreover, although many different phenomena are mentioned, explicit remarks about important differences between them (e.g. the electric and gravitational flux have no velocity) are explicitly stated.

The following transcripts from the professor's discourse and their corresponding categorization complement the described analysis:

18:20	We speak about flux through a surface. […] If the direction of the normal to the surface varies, the flux also changes. (M1, V1)
26:00	Then we define flux by the surface integral of the projection, scalar product, between the vector I'm considering and the normal to the surface. (M2)
37:20	His question is very good. It indicates a confusion, but this always occurs with everyone who study this thing. If it did not occur with you, it's because you didn't realize it yet. It is occurring and you are not aware of that. (Met)
39:40	Every time you work in hydrodynamics – bees, water air – the flux represents something that passes through a surface. They took this mathematical formulation to use in many other cases […] But there are important differences. The gravitational field doesn't really flow, it doesn't have any velocity. It is there. (A2)

CONCLUSIONS AND PERSPECTIVES

When a physics teacher simply states the formula that describes a particular physical phenomenon and then uses it to solve standard problems he/she is actually making an enormous conceptual jump. In reality, he/she is usually underestimating the complex process of mathematization. A brief overview of the history of physics is sufficient to illustrate that the mathematization of this science was a long and complicated process (Bochner, 1981).

In this paper we aimed at stressing the complexity of the translation between the physical world and mathematics by analysing physics lectures on the concepts of charge density and electric flux given by a special professor. The central role of mathematization became evident due to the considerable amount of time dedicated to it. Essentially, this analysis evidenced the following strategies: a *from concrete to abstract* approach, an extensive use of visual representations and material analogies, explicit remarks on idealizations and metacognitive comments. It is not our intention to suggest that this should be followed as a "*how to*" guide, however we strongly believe that these results underline several obstacles of the complex road to mathematization, which should be taken into account in physics lessons.

As future perspectives of this research we intend to investigate other lectures - from this professor as well as from others - and compare their different patterns with the same analytical tool. An additional possibility is to investigate how similar themes are presented in didactical classics like Feynman lectures. With this work we envisage to derive promising strategies to teach the structural role of mathematics with the goal of including such discussions in physics teacher training courses.

ELEMENTARY TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE AND STUDENT ACHIEVEMENT IN SCIENCE EDUCATION

Kim Lange[1]*, Thilo Kleickmann*[2] *and Kornelia Möller*[1]
[1]University of Muenster, Germany
[2]Leibniz Institute for Science and Mathematics Education, Kiel, Germany

Abstract: The scope of this paper is to explore whether elementary science teachers' pedagogical content knowledge (PCK) in the content area "states of matter and changes of state" contributes to gains in elementary students' understanding of related concepts. The paper reports on a value-added study with a sample of 60 fourth-grade classrooms and their science teachers. The data derived from a project funded by the German Research Foundation (project "PLUS"). Teachers' PCK and student achievement concerning the mentioned scientific topic were directly assessed with tests. Multilevel regression analyses were conducted to analyze the significance of teachers' PCK for students' progress in elementary science classrooms. Results showed that teachers' PCK was significantly related to student achievement in elementary science after controlling for key student- and teacher-level covariates.

Keywords: teachers, pedagogical content knowledge, student outcomes, science education, hierarchical modeling

INTRODUCTION

In the research literature on teaching and teacher education, there is a shared understanding that teachers' professional knowledge is an important determinant of instructional quality that impacts students' achievement gains (Baumert & Kunter, 2006; Bromme, 1997; Munby, Russell, & Martin, 2001). Yet few empirical studies have assessed the different components of teachers' knowledge directly and separately to predict instructional quality or student outcome. The main goal of this study was to explore whether teachers' pedagogical content knowledge as a crucial component of teachers' professional knowledge makes a contribution to explaining differences in students' learning outcomes in elementary science education.

The study is part of the project PLUS (Teachers' professional knowledge, science teaching and student outcomes in the transition from primary to secondary school) that investigates conditions and outcomes of science instruction in the transition from elementary to secondary education. It was conducted in Germany from 2007 to 2010. The study, which had two measurement points, surveyed a sample of 60 elementary science classes and 54 secondary science classes and their teachers. Drawing on the elementary sample, the study at hand explored whether teachers' pedagogical content knowledge in science contributes to gains in students' understanding of scientific concepts. In order to address this question we used a newly constructed knowledge test to assess teachers' pedagogical content knowledge in the domain of science directly. Teacher data was then linked to data on student outcome, in order to determine the implications of pedagogical content knowledge for student learning.

RATIONALE

The theoretical foundation of research on teachers' professional knowledge was laid at the American Educational Research Association meeting in 1985, when Lee Shulman proposed a model for conceptualizing knowledge for teaching. There he introduced the constructs of generic pedagogical knowledge, content knowledge and pedagogical content knowledge as the core components of the specialized knowledge that is required for teaching. Although researchers have added to or specified these domains of teacher knowledge over the last decades, these three components have consistently appeared in literature and thus seem to be internationally agreed upon as core components of teachers' professional knowledge (Baumert & Kunter, 2006; Borko & Putnam, 1996; Bromme, 1997; Munby, Russell, & Martin, 2001). Knowledge of generic pedagogy (PK) is described as general, subject-independent knowledge about classroom organization and management, general knowledge of learning theory and general methods of teaching. Content knowledge (CK) includes the knowledge of a subject or discipline per se and is not unique to teaching. It goes beyond the knowledge of facts, concepts, principles and theories to also include an understanding of how concepts and principles of a subject are organized and the rules of evidence and proof that are used to justify claims in a certain subject or discipline. Within this classification of teachers' knowledge, pedagogical content knowledge (PCK) is considered the central component of teachers' professional knowledge that distinguishes teachers from subject matter specialists (Grossman, 1990; Shulman, 1987; Van Driel, Verloop, & De Vos, 1998). PCK is defined as a kind of "amalgam" of content knowledge with pedagogical and psychological knowledge as well as with the teachers' personal experiences, creating an understanding of how certain topics, problems or issues ought to be presented and adapted to the learners' different interests and abilities (Shulman, 1987). Magnusson, Krajcik and Borko (1999) proposed a model of PCK in the area of science education, defining five components. They include 'orientations towards science teaching', 'knowledge of science curricula', 'knowledge of students' understanding of science', 'knowledge of instructional strategies' and 'knowledge of assessment for science'. Recent studies on the different domains of PCK (e.g. orientations towards teaching, knowledge of students' understanding or instructional strategies) in mathematics found that teachers' mathematical PCK was positively related to students' gains in mathematical achievement (e.g. Staub & Stern, 2002; Hill, Rowan, & Ball, 2005, Baumert et al., 2010). Whereas studies in the domain of orientations towards teaching have already been established in the field of elementary science (Kleickmann, 2008), studies targeting at the further components of PCK are missing completely in elementary science. Thus, this study aims at measuring elementary science teachers' PCK directly, followed by examining its relevance for students' gains in conceptual understanding.

METHODS

Comprising 1326 fourth-graders (621 girls and 702 boys, 3 students did not indicate gender) in 60 classrooms, the data presented here stems from a project investigating the development and interplay of science instruction, classroom climate and students' science interest in the transition from primary to secondary education in Germany (PLUS Study). The cross-sectional study had a quasi-experimental design. Participating teachers were instructed to provide their classes with a series of three 90-minute lessons on the topic of evaporation and condensation. Students were tested for science achievement concerning the topic "states of matter and changes of state" both before and after the series of lessons. Teacher data were gathered from various instruments amongst others a test assessing their PCK in the domain of "states of matter".

The assessment of teachers' PCK was based on the Magnusson et al. model (1999). Considering the recent studies in mathematics that described 'knowledge of students' understanding' (KSU) and 'knowledge of instructional strategies' (KIS) as components of PCK that trigger students' achievement, the focus of the test was nested within these two components. The developed items asked teachers e.g. to list as many alternative students' conceptions as possible concerning an every-day evaporation situation (KSU). Other items presented situations in which teachers are asked to detect comprehension difficulties or to describe adequate behavior to promote insightful student learning (KIS). The final test consisted of 14 items (11 free-response-, 3 multiple-choice-items) and showed good psychometrical qualities (average ICC= .92, range: .8 - 1.0; Cronbachs $\alpha = 0.69$).

Student achievement was assessed at the end of the unit by a test covering condensation and evaporation as well as the liquid and gaseous state of matter (using water as example). The reliability of the full test (24 items in m*ultiple-choice*- or m*ultiple-select*-format) was Cronbachs $\alpha = .67$ in the pretest and Cronbachs $\alpha = .79$ in the posttest.

Multilevel analyses were used to analyze the impact of elementary science teachers‘ PCK on students‘ gains in conceptual understanding. A two-level model predicting the achievement on the posttest-score on the individual-level by teachers topic-specific PCK on the class level was specified. To account for other important predictors, we controlled for relevant student characteristic like prior knowledge, general cognitive abilities, German as native language, socio-economic background and gender as well as for critical classroom and teacher characteristics like duration of instruction, classroom-management and job experience. To account for missing data we used the full information maximum likelihood algorithm implemented in the software Mplus, which estimates the missing values (Muthén & Muthén, 1998-2009).

RESULTS

In a first step, the variance in students' achievement was decomposed into within- and between-class components. The results showed that 78.6% of the variation in achievement was within classes and that 21.4% was between classes. After controlling for the variables at the individual level, 14.4% of the variation in achievement remained between classes.

In a second step, we specified the individual model. We estimated a random intercept model with the five control variables named above. The most important predictor was that of students' topic-specific prior knowledge at the beginning of the unit, followed by general cognitive ability. Beyond that, German as native language, socio-economic background and gender proved to be less important.

In the next step, the control variables at the class level were entered in the model. The predictors at class level were: duration of instruction, quality of classroom-management and job experience. All variables proved to be significant predictors of students' learning achievement concerning "states of matter" at the end of the unit.

When PCK of elementary science teachers was entered in the model next to the control variables the results revealed a substantial positive effect of the measured PCK on students' gains in science achievement in the domain of “states of matter”. Thirteen percent of the variance in achievement between classes was explained by PCK after controlling for key student- and teacher-level covariates (for detailed analyses see Lange, Kleickmann, Tröbst, & Möller, in print).

DISCUSSION AND CONCLUSION

In the presented study we constructed and implemented a test to assess primary teachers’ PCK directly. In sum first analyses indicate that we succeeded in developing a reliable and valid test which was needed to answer our research questions on the impact of PCK on students’ achievement gains in elementary science classrooms. When controlling for several predictors at individual and class level, we were able to show that elementary science teachers’ PCK positively predicts students’ gains in science achievement in the domain of “states of matter”. These results are nicely in line with findings on effects of domain-specific knowledge in the field of mathematics (Baumert et al., 2010, Hill et al., 2005).

Compared to the effect sizes found in the studies in the domain of mathematics the effect sizes are rather small. It could be argued that this is a domain-specific effect. On the other hand the small effect size could be explained by the short treatment-duration of the study conducted. While the studies in the field of mathematics investigated the impact of teachers’ PCK on students’ learning gains over a whole school year, our study chose a topic-specific approach. Focusing on just one content area, we investigated the impact of teachers’ PCK on student achievement over an average treatment duration of approx. seven lessons. Against this background, the question whether the small effect size is a domain-specific effect or not, is not answered yet. Neither is the question whether we can find an impact of PCK on students’ achievement gains in other content domains within elementary science education. Further research in different science domains and studies over a longer period of time are needed to answer these questions. If these future research attempts confirmed our findings, one could tentatively conclude that it might be possible to improve students’ learning gains in science by improving teachers PCK. One of the next challenges for teacher research would then be to determine how pre-service and in-service teachers can best be supported in acquiring this knowledge.

SCHOOL CHANGE, TEACHER EDUCATION AND THE ROLE OF MENTORING

- A GERMAN APPROACH IN THE EUROPEAN PROJECT GIMMS –

Manfred Lang[1]
[1]Institute for Science Education IPN, Kiel, Germany

Abstract: Schools are experiencing a rapid change of educational practice with an increased demand of professionalism of teachers and teacher educators. Collaborative reflection and discourse in mentoring for teacher education are a basis on which change can occur. In the European GIMMS project (Gender, Innovation and Mentoring in Mathematics and Science) collaborative models of mentoring in science teacher education were studied. The German case study was used as an example of reform in teacher education allowing professional autonomy and critical feedback of teachers in a collaborative model. Beginning teachers accepted the partnership model of mentoring but only within limits concerning cooperation beyond the beginning teacher-mentor relationship. As a reason regularly changing partnerships were noted with unclear requirements of mentors and teacher educators. The many contacts of the beginning teachers do not in advance challenge an innovative mode of reflective teacher education. However mentors seem to operate predominantly with a reflexive mentoring model.

Keywords: mentoring, innovation, collaboration, teacher education, science.

SCIENCE EDUCATION IN TRANSITION

Schools not only in Germany but all over Europe are experiencing a rapid change of educational practice in accordance with reform requirements and demands. In order to guide these innovative processes modern solutions in teacher education need to be traced. In educational reform increased professionalism of teachers and teacher educators is of high importance: "What teachers know and can do is crucial to what students learn" (Darling-Hammond, 2000). Programs for professional development, teaching standards or advisory systems in teacher education comprise approaches to change in schools. But what kind of skills and knowledge base are needed for the teaching profession and what kind of support in the process of change?

In science education we see an emphasis on formal reasoning: systematic and disciplined approaches to the teaching of higher order thinking skills (Olson, 2002). Attempts to integrate ideas from outside the sciences or a discourse across or beyond boundaries of science subjects tend to be resisted in traditional practice. But it is not only subject matter knowledge or academic training that account for good teaching. Collaboration among stakeholders and its transformative power of curriculum change is seen as an important element of innovation. This requires professional autonomy and support for discourse between equals of different professional knowledge in school practice. Collaborative reflection and discourse in a network of practitioners and stakeholders is the basis on which change can occur.

A discourse across subjects, in which the value of practice is discussed, not only entails thinking about reorganising subject matter, but finding ways to justify those values for the socialization of learners as citizens and the perpetuation of a society's cultural norms and values. How to achieve this kind of discourse in school systems?

Mentoring in teacher education is seen as chance to generate reflective collaboration leading to innovative processes. Cochran-Smith and Paris (1995) argue that alternative visions of mentoring beyond traditional transmission models are needed to support teachers in collaborative mentoring and reflective practice. There are different perspectives of mentoring represented in models such as described by Maynard & Furlong (1995). They distinguish the apprenticeship, the competency and the reflective model. In our case the *reflective model* is of special interest for innovation in educational. It reflects a partnership based collaboration of initial and in-career teachers and mentors within a community of learners at school, exploring practical experiences in class in a flat hierarchy. However, this process of teacher engagement is not easily achieved. Usually the system of teacher supervision does not allow professional autonomy and collaboration of teachers. The function of teacher supervision is part of a system assessing success in system-wide achievement standards. Such management of teachers does not foster constructive engagement in change. But how can teachers become actors in curriculum reform?

INNOVATION AND COLLABORATIVE MENTORING IN THE GIMMS PROJECT

The European project GIMMS (Gender, Innovation and Mentoring in Mathematics and Science, Mooney & Lang, in preparation) was undertaken against the backdrop of PISA 2003 to 2009 (Klieme et al., 2010) and the teacher policy study "Teachers Matter" (OECD, 2005).

Trends in PISA for each country over the years indicate changes in time possibly due to changes in the educational systems. The OECD (Klieme et al., 2010) interprets this finding that PISA results over a period of years show whether school systems are becoming successful or not in helping students attain an understanding of life in modern society. Concerning gender results, in mathematics boys outperform girls and in science boys and girls perform about the same. The reasons due for these results are manifold. PISA analyzed some of them such as changes in resources, opportunities to learn, standards, achievement assessment or social climate. The quality of teaching was not controlled but seen as a central challenge of the school systems:"There is a lot of evidence, that the professional development of teachers is an outstanding resource for the quality development of the educational system". (Klieme et al, 2010, p. 296; translated from German). These PISA comparative achievement scores and the insight about the importance of teacher professional development were a starting point for curriculum innovation and inclusion work of the GIMMS project.

In the GIMMS project, coordinated by the University of Limerick, collaborative models of mentoring were used to introduce and study innovation in science teacher education. Seven case studies from Ireland, Spain, Germany, Czech Republic, Denmark and Austria demonstrate a big diversity of presuppositions in educational systems and project assumptions and expectations about innovation and teacher education.

Collaboration in the project was mostly realized in small scale mentor-mentee dyads, but also in occasional collaborative groupings of mentors, experienced teachers, teacher educators and groups of mentees. This will be a challenge for schools to support a regular setting for collaborative exchange.

The theoretical framework of this study is curriculum as political text with deliberative discourse for innovation (Aronowitz and Giroux 1991) inside a web of democratic mentoring relationships of learning with colleagues and teacher educators. This implies border crossing of diverse cultures that in a curriculum process of innovation and change. This argument positioned the work of curriculum innovation in each national system or part of it as a cultural field of discourse with diverse voices (Giroux & McLaren 1986). Voice develops through a physical and intellectual journey beyond boundaries of classroom, of disciples, of culture, of home and school learning. This means that curriculum innovation is justified by shared meaning making with a diversity of voices or stakeholders from a variety of communities in open 'public spaces' and not by top down decisions such as national curricula, prescribed standards or unreflected expert statements.

Elaborating research questions about innovation and mentoring

The GIMMS project has one of its focuses on differences and similarities of mentoring in the participating European countries and will use these insights to develop and pilot mentoring relationships between initial and in-career teachers in physics, chemistry, biology, and mathematics. Hence one of the key research questions to drive the project was: How can we develop better partnerships between initial and in-career teachers for continuing professional development and innovation?

Structure and methods of the GIMMS case study

In the GIMMS project national coordinators delivered national and progress reports during a period of three years and participated in interviews. In a final interview they were asked core questions about their national policy with regard to science and mathematics education and innovation, pedagogical practices and changes and models of mentoring. Some of these questions may get us closer to a better understanding of innovative processes and the role of teachers. Outcomes from this will not be offered here in detail but be used as a basis for further analysis of the national case study in Germany as an example.

In all the national cases innovation was judged to be central and during the three years' time of the project realized successfully. Interactions established a stable structure for exchange, generation of new ideas and innovation. The cooperation with teachers triggered discussions about different ways of teaching and mentoring as innovation within different curricular frameworks. This would not have happened in isolated school or university cultures.

INNOVATION AND MENTORING: THE GERMAN CASE STUDY AS AN EXAMPLE

In spite of all the national differences in background and dynamic of innovation in teaching and teacher education there is one consistent driving factor in every of the cases: the interaction of engaged teachers with a university or research and development institution. This answers the question, how teachers become actors in curriculum reform: As actors they need collaborative partnerships to cross boundaries of narrowed school practice.

In the *German* case study student teachers agreed that the intended reform in teacher education allowed professional autonomy and critical feedback of teachers with regularly changing partnerships but this produces some confusion by forcing them to obey different masters in school and state institutes. Teacher trainers from the state institute IQSH (institute for quality development) and researchers from the national institute for science education (IPN) worked with beginning teachers in the second phase and mentors at a school of these teachers. The idea of the Schleswig-Holstein model was to get away from the old model of study seminar, where only one expert teacher was the main contact person for the beginning teachers moving away from an apprenticeship model toward a more reflective model. The new approach used training modules offered by different persons of the IQSH. Beginning teachers have to learn about these modules and get support from the persons responsible for the module in the IQSH during school visits and mentors at school. The new idea of the work in Schleswig-Holstein with modules and mentors is to be more reflective in teacher education. Questions arise, how this model supports reflective mentoring, how mentors are qualified to participate in reflective practice and what kind of background beginning teachers were bringing to the school as reflective partners.

Method of tracing innovative aspects of mentoring and gender differences

Six beginning teachers and one mentor of a secondary school in Schleswig-Holstein were asked to participate in the study during the time period of August 2008 and November 2009.

At first a mentor was asked in an interview about the newly introduced official teacher education concept and its adaptation at school, the main tasks of the mentor and the coordinator at the school, the training and certification of mentors. In addition the mentor assembled documents about state requirements for the certification of teachers, the school concept about teacher education and guidelines from the coordinator.

In 2009 a second point of data collection followed with a questionnaire and semi structured interview for beginning teachers. Questions were raised about topics in teacher education, support of beginning teachers' work, collaboration, autonomy and workload in daily practice, gender specific differences and factors for success or failure of beginning teachers. In addition the beginning teachers were interviewed about their experience with the teacher education system and the mentoring process.

In order to trace these questions the model in figure 1 with reflective elements of collaboration was developed:

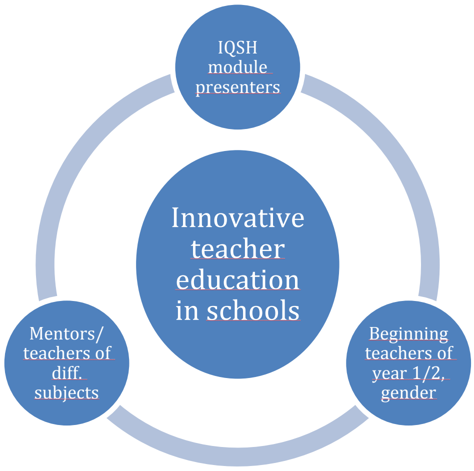

Figure 1: collaborative model about innovative teacher education in schools

In this model the complete system of reflections between mentors/teachers, beginning teachers and module offers of the IQSH teacher training institute for innovative teacher education is outlined. Each outer circle represents a community of educational actors that can interact through boundary crossing with a neighboring community. Within each circle further subsystems can be identified: teachers with or without a mentor status, teachers with different subjects, beginning teachers of consecutive years of training and different gender. It helps to interpret the kind of interactions in statements from questionnaires and interviews done.

RESULTS

Beginning teachers can choose modules in different subjects and educational topics. Persons from the IQSH present these modules in courses during a full work day in different places. Different modules can be offered by different presenters having different ideas about teaching principles and these teaching principles can be favoured differently by different mentors. Mentors are not always acquainted with the new modules in advance, but they are cooperating with the beginning teachers for preparation of lessons, more often on different levels such as offering practical advice and teaching outlines or discussing typical beginners' mistakes.

A problem with this system of modules is seen in the change of presenters and examiners. Beginning teachers do not have only one person for reference with publicly accountable expectations for their trial lessons and final examinations. This was judged to be more favorable in the old system where there were study guides in fixed groupings. In addition presenters of modules at the education institution and mentor teachers at the school do not have the same background and competencies. Mentors only have a general preparatory introduction into their tasks. These tasks are not related to specific goals for preparation of beginning teachers. A more specific training for mentors is judged to be more favorable.

Beginning teachers' answers in questionnaires and interviews partially reflected these critical points of missing coherence between theory in modules and school practice and contradictory demands for examinations. In the questionnaire they agreed that the modules for their subjects were helpful and that they got sufficient support and time for lesson preparation from the school. But they did not find some help in the modules about pedagogy and did not have enough time to cooperate sufficiently with the mentor teacher at the school or to discuss their work or experiences sufficiently with other beginning teachers.

Collaboration was not complete concerning the elements of the above model in figure 1 about innovative teacher education. Collaboration, reflection and exchange, in the larger more extended professional network, between the module presenter, beginning teacher and mentor teacher gives a chance of specific learning for all while linking theory of modules with the practical situation in the classroom. In an interview a beginning teacher is complaining about a lack of specific preparation of mentors for this networking:

> *"In general mentors are not well trained. This is obvious ... we as beginning teachers experience, that we are trained very well for the module and then we give our knowledge to the mentors ... They don't know much and in our meetings for consultation the mentors are those, who can say the least about the given lesson. There should be done more so that trainers become trainers, which are now simple teachers who guide us – nothing more."*

To a certain extent a culture of cooperation and autonomy seems to be fostered through partnership based mentoring. Especially beginning teachers from Schleswig-Holstein report a relatively high degree of autonomy and satisfaction about cooperation with colleagues. But the opportunities for beginning teachers to discuss their work with mentor teachers were estimated to be low. Nonetheless it was lower-order co-operation on the practical and technical aspects of professional work that seemed to dominate the mentoring process.

Content of subjects and its theory in modules seem to be separated from school practice. It clearly needs to be elaborated in congruence with mentor teachers. This point is explicitly made in the following statement:

> *"This is absolutely separate. There is something demanded from us by the IQSH [State Institute for Quality Insurance in Schleswig-Holstein] and what we are discussing there with other beginning teachers. And then there is the school, what happens there. And this is completely separated, which is a problem. On the one side we have to do what the module presenter is demanding from us, starting from educational standards, competencies and goals and on the other side in the school they say – pfff – curriculum, educational standards. This is mostly of no interest; they do not know what a curriculum is."*

Beginning teachers marked in the questionnaire that they missed to a high extent that the module presenters and others as examiners explained the criteria for the examination and that they did not get sufficient help for the examination paper at home. Concerning the demands from module presenters, mentors and the headmaster they feel that they have had to serve different masters with many opposite requirements.

As already mentioned the standards based modules are usually not well known by mentor teachers or principals at the school. This became a problem of agreement between this group of people responsible for the preparation and certification of examinations. In addition different modules may be offered by different presenters having different ideas and ideologies about teaching principles. These teaching principles might then be favored differently by different mentors as reported:

> *"The module presenters are not in agreement with their requirements at the end, although there are standards for that and information for preparation defining the criteria for correcting our exam home work ....One time it was required that I show my professional development as a teacher, what I have leant, how did I manage the lesson and how I profited from that personally. In the other homework I had to show how I supported the pupils, how did I use different criteria for the development of pupils? These are completely different tasks.... This is the point with the mentor that we shall do what we are required but he is not interested in educational standards or methods, there is only interest in subject matter, subject matter, subject matter. "*

A possible solution to bring greater levels of coherence to these divergent views might be to have a better collaboration between the various actors as suggested in the interview:

> *"I have experience about better exchange, defining the other mentor type. I always found out that mentors liked to get material we brought from the modules.... And I believe that it is meaningful that mentors and beginning teachers go together to module meetings. This I have done once with a Math mentor. This is something different, if you meet and can talk together about it."*

Beginning teachers personally experienced gender differences during their social interactions with the range of actors in their teacher education. They were asked a key question in this regard: How are male and female beginning teachers treated differently? The beginning teaches, especially the female beginning teachers, experienced a difference. They were complaining that their gender made a difference in discussions as pointed out:

"I experience a higher richness, when men are sitting with us in module sessions. This brings more objectivity in or another point of view, which is not too female."

Female beginning teachers said that they were treated differently in some ways. When there were only female beginning teachers together, discussions were completely different in the sense that there was no rigorous and a less aggressive demand.

In summary beginning teachers in Schleswig-Holstein seem to experience a high degree of support in their school. Nonetheless there is very little cooperation between initial teachers, beginning teachers and experienced teachers, other than with their specifically nominated mentor teacher. The partnership model of mentoring favored in Schleswig-Holstein does not seem to influence or even foster a culture of cooperation beyond the beginning teacher-mentor teacher relationship. The beginning teachers report very little collaboration within the full community of teachers at the school. There were few reported examples of higher order co-operation. Discussions on teaching experiences and lesson plans were scarce. Cooperative lesson planning rarely ever happens.

The many contacts of the beginning teachers do not in advance challenge an innovative mode of reflective teacher education. However many of the beginning teachers express themselves in the interviews in such a way that the mentors operate predominantly with a reflexive mentoring model.

A possible solution of these divergent views might be a better collaboration as suggested by one teacher. In this case collaboration and exchange between module presenter, beginning teacher and mentor is seen as a chance of specific learning for all, linking theory of modules with the practical situation in the classroom.

PERCEIVED PROFESSIONAL DEVELOPMENT NEEDS FOR SAUDI ARABIAN SCIENCE TEACHERS

Nasser Mansour[12]*, Saeed Alshamrani, Abdulwali Aldahmash*[2] *and Basil Alqudah*[2]
[1]Graduate School of Education, University of Exeter, UK
[2]The Excellence Center of Science and Mathematics Education, King Saud University, Saudi Arabia

Abstract: This research looks specifically at the perceived professional development needs for science teachers, so that continuing professional development (CPD) can be planned and implemented. The prime aim of this study was to ascertain the perceived needs of Saudi Arabian science teachers and science supervisors practicing in elementary, middle, and secondary schools. Science teachers were characterized by gender, school location, and area of specialization. The main instrument used was a questionnaire. The validity and reliability of the instrument were systematically established through relevant test procedures. The questionnaire seeks feedback on the main aspects of science teachers' needs, including generic pedagogical knowledge and skills, knowledge and skills in science subjects, managing and delivering science instruction, diagnosing and evaluating students, planning science instruction, administering science instructional facilities and equipment, integration of multimedia technology, and informal science learning. Additionally, the questionnaire covered the key science subject domains in which science teachers might need professional development. This study argues that science teachers' voices concerning their professional development needs are the key guide for their CPD.

Keywords: Teachers' professional development needs- Continuing Professional Development- Teacher Education

INTRODUCTION

Teacher professional development is a prominent feature on the educational landscapes of developed and developing countries equally. Experience around the world in developing, industrialized, and information-based countries has shown that professional development is the key determining factor for improved student performance. Effective professional development experiences are designed to help teachers build a new understanding of teaching and learning (Lee, 2001). Teacher development can be conceptualised as a mechanism for driving change in educational systems and/or as a strategy for empowering individuals and teams to improve their professional knowledge and pedagogy (Day & Sachs, 2004). Dillon (2010) argues that teacher development can either play a critical role in meeting teachers' needs and wants, or it can frustrate teachers and keep them from reaching their full potential. He also argues that teachers might both want and need professional development. In contrast, someone in a different profession, such as an inspector or a line manager, might identify that an employee has a need that they themselves are unaware of, such as a need for training in different questioning techniques. Nevertheless, for the purposes of this paper, we will explore the difference between the needs required for teaching science effectively represented by the inspectors' opinion, and the needs of teachers.

The continual deepening of knowledge and skills is an integral part of the development of any professional working in any profession. One important means of achieving competitive advantage is the creation of conditions for the rapid acquisition of new knowledge and skills. Teaching takes place in a world dominated by change, uncertainty and increasing complexity. Government publications all over the world, in Europe, North America and the Antipodes stress the technological, economic and social challenges which schools, and therefore teachers, face (Day, 1999). From the professional development view, Borko and Putnam (1995) argue that current educational reform recommends a shift toward a student-centred paradigm. This entails a substantial departure in teachers' approaches, from a traditional transmission of knowledge to a cognitive and social construction of knowledge. The tradition of 'in-service days' as the norm in professional development has been criticized as inadequate and inappropriate in the context of current educational reform efforts, and as being out of step with current research about teacher learning (Darling-Hammond & McLaughlin, 1995). One possible reason for the unsatisfactory results of in-service teacher training might be that the objectives of programmes were not congruent with teachers' personal and classroom needs (Baird et al., 1993). It might be reasonable to better understand the target audience before prescribing any intervention. Thus, to simply impose a training programme on teachers without considering their needs makes little sense (Noh, Cha, Kang, & Scharmann, 2004). Baird and Rowsey (1989) also highlight teachers' complaints that much time spent during in-service programmes and activities was wasted when such programmes did not meet their respective classroom needs. Loughran and Invarson (1993) argue that it is important that as a profession we are able to articulate what science teachers need to know and are able to do.

The concept of need has diverse interpretations. In the literature 'need' is used variously to mean a discrepancy, a recognized problem, the requirement for more services, and the wants of people (Stufflebeam, Mc Cormick, Bronkerhoff, & Nelson, 1985; Packwood & Whitaker, 1988). For this study, need is defined as the wants or preferences of an individual or a group of people. Need in this context is seen as a want (which implies interest or motivation) felt by an individual or group to eliminate a lack (Queeney, 1995). Without identification of teacher needs, poorly directed and inadequately focused interventions may emerge (Rhodes & Beneicke, 2003).

Educators acknowledge that the quality of science instruction is the main factor in developing meaningful understanding of science. Furthermore, the quality of science instruction cannot be achieved without qualified science teachers (Carey, 2004). Therefore, any mature reform of science education should emphasise science teacher professional development programs . These programs should help teachers develop in-depth knowledge of their disciplines as well as pedagogical content knowledge and skills (Mansour, 2010b). Consequently, the professional development of science teachers is widely recognised as a national priority (Obikan for Research and Development, 2010). The Excellence Center of Science and Mathematics Education ECSME at King Saud University in Saudi Arabia considers research in the professional development of science teachers as a key element in the reforming process of science education in Saudi Arabia. Therefore, ECSME launched a group to conduct a series of researches with science teachers and science teacher supervisors to develop a continuing professional development (CPD) program. The purpose of the program would be to support science teachers to take an active role in science education reform in Saudi Arabia. Accordingly, in the current study the research group aimed to identify and explore science teachers' needs in both content and pedagogical knowledge and skills as a first step toward making decisions and recommendations about the elements of CPD program(s) required for science teachers. The following two research questions were used:

1. What professional development needs in science content knowledge are identified by science teachers and their supervisors in Saudi Arabia?
2. What professional development needs in pedagogical knowledge and skills are identified by science teachers and their supervisors in Saudi Arabia?

METHODOLOGY

Instrumentation

To collect the data, the researchers developed a questionnaire based both on their experiences and on a review of a related study. The questionnaire includes 40 items (21 items for the science content knowledge domain and 19 items for the pedagogical knowledge and skills domain). Cronbach's coefficient alpha was used to calculate the internal consistency coefficients of the questionnaire. Results of the reliability analysis showed that the items in the instrument had a satisfactory discriminating power. Reliability coefficient alpha obtained for the whole instrument was 0.973; however, the coefficient alpha for the two scales were 0.978 and 0.973 respectively for the science content knowledge domain and the pedagogical knowledge and skill domain.

Collection of Data and Sampling

The population of this study included 2701 Saudi science teachers and 66 science teacher supervisors in four educational districts in different parts of Saudi Arabia (Jeddah, Alkarj, Alzulfi, and Almeqwah districts). These districts were chosen because they were parts of the partnership program with the Centre of Science and Mathematics Education which is the sponsor for this study. All science teachers in these districts were considered as the population and the sample of this study; a representative was hired in each educational district to distribute the questionnaire to all science teachers and supervisors in each educational district. A total of 499 Saudi science teachers and 61 science teacher supervisors responded to the questionnaire. For science teachers, the respondents included both sexes: 209 (42%) were female and 290 (58%) were male. Concerning subject specialism, it was found that the respondents were drawn from the following disciplines: biology 33.3%, physics 16.6%, chemistry 16.4%, earth sciences 2.0, other subjects (those who teach since for elementary students, but are not specialized in science) 27.1%. The 61 science teacher supervisors included both genders: 48 (78.7%) were female and 13 (21.3%) were male.

FINDINGS

The needs in science domains perceived by teachers and supervisors.

Table 1 summarizes the perceived needs of science teachers and their supervisors for professional development in various science subjects. As shown in Table 1, the 10 top needs perceived by teachers were the following: 1. nature of science and scientific inquiry, 2. modern physics, 3. structure and function of human systems, 4. genetics and evolution, 5. Electricity and magnetism, 6. earth properties and physical processes, 7. chemical reactions, 8. Forces and motion, 9. energy and 10. energy and chemical changes. These needs had a sequential priority mean of 3.53, 3.47, 3.46, 3.45, 3.43, 3.42, 3.41, 3.41, 3.40, and 3.39, respectively. In contrast, the 10 top needs perceived by science supervisors were the following: 1. the solar system and the universe, 2. Nature of science and scientific inquiry, 3.

Forces and motion, 4. plants, 5. climate and weather, 6. Structure and properties of matter, 7. Genetics and evolution, 8. Chemical reactions, 9. Earth properties and physical processes modern physics and 10. Energy and chemical changes.

These needs had a sequential priority mean of 4.51, 4.41, 4.25, 4.15, 4.02, 3.98, 3.94, 3.89, 3.80, and 3.78, respectively. Six out of the top 10 perceived needs were the same for both science teachers and their supervisors. These six needs are Genetics and evolution, energy, forces and motion, energy and chemical changes, chemical reactions, Earth properties and physical processes, and the nature of science and scientific inquiry. However, as shown in Table 1 the priority among these six perceived needs was different for science teachers and science supervisors, except for energy and chemical changes, which was ranked 10 by both science teachers and science supervisors. These findings might raise important questions about the validity of the science supervisors' voice regarding the CPD required for teachers. They also raise a question about the science supervisors' awareness of the science teachers' needs.

Table1
Science subject knowledge perceived by science teachers and by supervisors

No	Items	Science teachers		Science supervisors		t	df	Sig. (2-tailed)

The number in parentheses represents the priority of the perceived need

An independent sample t-test was conducted to see whether there was a difference between teachers and supervisors in their perceptions of teachers' CPD needs in science domains. As shown in Table 1 there was not a statistically significant difference, except on three subject knowledge questions: living things, energy and structure of matter, and chemical bonding. The means of supervisors' responses of these three domains (3.33, 3.47, and 3.46, respectively) were higher those of teachers' perceived needs to the same topics (3.33, 3.40, and 3.36, respectively). This can be explained by the fact that the supervisors do not hold sufficient knowledge about teachers' needs concerning the science domains.

The needs in pedagogical knowledge and skills perceived by teachers and supervisors.

Table 1 summarizes the perceived needs of science teachers and science supervisors for professional development on pedagogical knowledge and skills. As shown in Table 2, the 10 top needs perceived by teachers were the following: 1. teaching science through field trips and scientific visits, 2. developing creative thinking among students, 3. teaching science for gifted students, 4. developing Science concept among students, 5. associating technology with teaching, 6. planning for teaching, 7. scientific inquiry instruction based in science, 8. Teaching science for special need students, 9. instruction based problem solving in science and 10. using concept mapping. These needs had a sequential priority mean of 3.68, 3.66, 3.64, 3.60, 3.57, 3.55, 3.54, 3.52, 3.51, and 3.50, respectively.

Table 2

Need of Pedagogical knowledge and skills as perceived by in-service science teachers and supervisors

No	Items	Science teachers		Science supervisors		t	df	Sig. (2-tailed)
		M	SD	M	SD			
1	Teaching theory, such as constructivism, behaviourism	3.50 (10)	1.038	4.28	.878	5.756	549	.000
2	Classroom management skills	3.28	1.155	4.38 (10)	.840	7.271	554	.000
3	Associating technology with teaching	3.57 (5)	1.122	4.36	.817	5.497	547	.000
4	Using labs in teaching science	3.55 (6)	1.189	4.46 (8)	.773	5.823	549	.000
5	Assessing students' learning	3.33	1.127	4.16	.970	5.520	548	.000
6	Planning for teaching	3.28	1.148	4.13	.903	5.748	551	.000
7	Connecting science to students' real lives	3.32	1.207	4.70 (2)	.691	8.688	550	.000
8	Scientific inquiry instruction based in science	3.54 (7)	1.113	4.69 (3)	.564	7.794	547	.000
9	Instruction based on problem solving in science	3.51 (9)	1.091	4.05	.884	3.894	549	.000
10	Using concept mapping	3.45	1.102	4.16	.840	5.072	544	.000
11	How to teach specific science topics, such as magnetism or writing chemistry equations	3.38	1.099	4.30	.955	6.138	554	.000
12	Questioning and classroom discussion techniques	3.32	1.176	4.42 (9)	.747	6.968	553	.000
13	Teaching science through field trips and scientific visits	3.68 (1)	1.111	4.74 (1)	.480	7.230	547	.000
14	Developing creative thinking among students	3.66 (2)	1.041	4.52 (7)	.748	6.066	546	.000
15	Developing science concepts among students	3.60 (4)	1.018	4.68 (4)	.596	7.873	541	.000
16	Teaching science for gifted students	3.64 (3)	1.074	4.56(6)	.643	6.771	540	.000
17	Teaching science for special needs students	3.52 (8)	1.183	3.98	.904	2.904	545	.004
18	Content analysis	3.42	1.040	4.60 (5)	.588	8.634	544	.000
19	Teaching science using learning cycle	3.49	1.052	3.95	.825	3.256	542	.001
20	Connecting science to other courses	3.41	1.093	4.00	.876	3.968	540	.000
21	Connecting science topics to each other	3.44	1.110	4.28	.878	389	484	.697

The 10 top needs perceived by science supervisors were the following: 1. teaching science through field trips and scientific visits, 2. connecting science to student the real Life, 3. scientific inquiry instruction based in science, 4. developing science concept among students, 5. content analysis, 6. Teaching science for gifted students, 7. developing creative thinking among students, 8. using labs in teaching science, 9. questioning and classroom discussion technique and 10. classroom management skills. These needs had a sequential priority mean of 4.74, 4.70, 4.69, 4.68, 4.60, 4.56, 4.52, 4.46, 4.42, and 4.38, respectively. Six out of the top 10 perceived needs were the same for both science teachers and supervisors. The six needs are these: 1. using labs in teaching science, 2. scientific inquiry instruction based in science, 3. teaching science through field trips and scientific visits, 4. developing creative thinking among students, 5. developing science concepts among students, and 6. teaching science for gifted students. However, as shown in Table 2 the priority among these six perceived needs by both science teachers and science supervisors was different, except for Teaching science through field trips and scientific visits, which was ranked 1 by both science teachers and science supervisors.

An independent sample t-test was conducted to see whether there was a difference between teachers and the supervisors in terms of teachers' CPD needs for pedagogical knowledge and skills. As shown in Table 2 there was a statistically significant difference between teachers' and supervisors responses, except that there was not a significant difference on one item—Connecting science topics to each other. The means of supervisors' responses on these three domains (M = 4.28) were higher that of teachers' perceived needs for the this skill (M =3.44). This can be explained by the fact that the supervisors do not hold sufficient knowledge about teachers' needs concerning the science domains.

DISCUSSION AND IMPLICATIONS

The majority of the teachers in the current study expressed a great need for academic and pedagogical training. The findings reflected that teachers perceive that they lack basic knowledge (e.g., chemical bonding, structure and properties of matter, forces and motion, and structure and function of human systems) and skills (e.g., planning for teaching, using labs in teaching science, and scientific inquiry instruction in science) to teach science. These findings might be interpreted as meaning that teachers believed their pre-service and in-service education did not help them in teaching science as it should be taught. Therefore, science educators should be aware of science teachers' professional needs in both pre-service and in-service training to use the pedagogies that can promote these 21st century skills e.g. teaching science for creative thinking, teaching science for gifted students, teaching science through field trips and scientific visits, connecting science to students' real lives etc.

The results from this study indicate that there is a mismatch between teachers' perceptions of their CPD needs and their supervisors' perceptions. While teachers are particularly concerned with the quality of science education, other stakeholders, such as science supervisors in this study, may have different priorities. In this sense, the findings of the current study concur with Park Rogers et al. (2006)'s study that the difference in beliefs among the stakeholders of professional development PD that has contributed to the gap between ideal and actual PD practice. Park Rogers et al (2010: 313) argue that "individual orientations to teaching science teachers do exist, can impact science teacher education activities, and can also change". A balance is required that addresses the concerns of everyone involved by reconciling competing interests. In this sense, Clandinin (1992, p.136) argues that teacher education should involve 'highlighting the tensions between personal and institutional narratives' so that reflection can be made to be powerfully relevant through focusing on the contrast between how teachers and institutions see each other and how they see themselves. Additionally, teachers' voices should be heard and taken into account concerning their perceived professional needs and the practical problems they face when implementing any new ideas in the classrooms.

The present study provided an insight for science teacher education. It will be useful for science teacher educators since it aims to meet science teachers' professional needs. According to Mansour (2010b), one reason why previous science education reform efforts have failed is because a consistent and coherent set of purposes, policies, programmes, and practices do not exist. Setting policies or curriculum frameworks at the state, county or even the school level can influence practice in the classroom, but may not ensure that science teachers will appropriately or consistently translate the policies into practice (Mansour, 2010a). Therefore, science teachers, supervisors, policy makers, and in-service and pre-service programme planners need to work together to consider the recommendations that have been identified in the teachers' professional development research.

Abstract: This article discusses science teachers' perceptions of their own experiences in research or innovative programs, identifying positive and negative aspects of these experiences. Data was collected from 1290 science teachers within a large-scale questionnaire of TRACES project, developed in collaboration with universities from Argentina, Brazil, Colombia, Israel, Italy and Spain. Results showed around half of the teachers (44.7 %) have participated in some kind of innovative or research experience. These experiences are strongly cultural dependent. The high frequency on innovative programs (36,4%), which are usually proposed by public policies, indicates the teachers conception of innovation as produced externally, as something that is received in the school and reproduced (top-down). Teachers seem to assume a passive role in this process. The positive perceptions of these experiences were organized in the following categories: professional development; increasing in teachers and students autonomy; opportunities to develop peer-to-peer learning and good practices exchange; improvement of teachers' reflexive thinking; fitting the content to the context; development of procedural and attitudinal students learning; development of student's conceptual learning; and opportunities to experience research methodologies. The negative perceptions about teachers' participation in research were: lack of time and material resources; lack of engagement of the school community; lack of continuity and information about research results; lack of training and experience in research; administrative obstacles; and lack of connection between research and school context.

Keywords: teachers' perceptions; research experience; innovative experience; science education; TRACES.

BACKGROUND AND PURPOSE

This article presents partial results produced from the project TRACES - Transformative Research Activities: Cultural Diversities and Education in Science, funded by FP7[1], developed in collaboration with universities from Argentina, Brazil, Colombia, Israel, Italy and Spain. This project aims to identifying in each country the difficulties to bridge the gap between science education research results and the actual application of these results in teaching practice in schools. Within a transformative perspective, it also aims to involve all the actors (teachers, students, parents, researchers and policy makers) in the development of significant practices; as well as the elaboration of guidelines in order to improve scientific education.

TRACES project was structured in three main stages. During the first stage, in each partner country, consortium members carried out a survey of policies for science education improvement (national plans, projects and experimentations, curriculum reforms, institutional guidelines) implemented at national level during the last years. A parallel survey investigated the perspectives of

[1] TRACES: Transformative Research Activities, Cultural Diversities and Education in Science. *FP*7-*SCIENCE-IN-SOCIETY*-2009-1-*244898.*

the different actors (policy makers, teachers, researchers) involved in this process about the impact of those initiatives and of science education research, the possible barriers on the path towards their translation in actual teaching and learning practices at school. In the second stage, the consortium planned field actions in each partner country, inspired by the rationale shared in the first stage of the project and by research findings. The actions were designed and carried out by local project groups, involving the actors in an action-research process. In the third stage, lessons learned from the two previous phases will be put together and brought to a common ground at the consortium level, in order to compare results and come to a common reflection.

This article presents a development of the first stage of TRACES project, in which the science teachers' perceptions about their own experiences in research or innovative programs, as well as the positive and negative aspects of these experiences are investigated.

The research questions that guided this study were: (1) What are the science teachers` experiences in research or innovative programs? (2) What positive aspects are identified by the science teachers in their experiences in research or innovative programs? (3) What negative aspects are identified by the science teachers in their experiences in research or innovative programs?

RATIONALE

Different hypotheses have been investigated to account for a perceived lack of connection between research and practice. Hargreaves (1996, cited by McIntyre, 2005) complained that researchers often determine the agenda for educational research, and teachers are not even seeing the lack of evidence-based research as a problem in urgent need of remedy. For McIntyre (2005), the knowledge needed by classroom teachers in their everyday work and the knowledge that educational research is well equipped to provide are of two different kinds. Research-based knowledge may be used as a contributing element to pedagogical knowledge, but it cannot be simply translated into pedagogical knowledge. Teachers use to give priority to practicality, while researchers are obliged to prioritize values relating to the clarity and coherence of arguments and to the truth of their conclusions. The nature of research-based knowledge is impersonal and the nature of teaching is highly personal.

There is a myth suggesting that science teachers in the primary and secondary schools do not want to hear about educational research related to their field. Luft (2010) states that teachers are interested in talking to colleagues about emerging issues in science education, and to participate in science education research. While there are science education researchers and teachers who bridge the gap research-practice, few projects have significant collaboration in order to produce a shared product.

As pointed by McLaughlin and Black-Hawkins (2004), teachers use to see the conducting of research as an add-on activity, while colleagues from university consider schools as simple sites for their research. However, the authors present several patterns or models of school-university research partnership, from research conducted by individual teachers and their students to research conducted by teachers and academics for the wider audience of educational community.

The distinctions between schools and universities do not necessarily cause conflict, nor do they necessarily act as barriers to different forms of knowledge generation. However these partnerships are most successful where there is a shared understanding of these differences, as well as an acceptance of the appropriateness of one another's concerns, a readiness to be helpful wherever possible, and a recognition that each could learn much from the other (McLaughlin & Black-Hawkins, 2007).

The main challenges and dilemmas for all those engaged in collaborative school-university research are mainly the conditions to support the research activities, the roles of teachers and academics, and the nature of knowledge created. This article enquires the nature of these challenges from the teachers' perceptions with respect to their own views and experiences in research and innovative programs.

METHODOLOGY

This paper presents a qualitative research (Lüdke & André, 1986; Bogdan & Biklen, 1994; Flick, 2009) and it was based on science teachers answers for one question posed in the TRACES large-scale questionnaire, containing 36 questions, including opened and closed questions, applied to the six countries of the consortium: *Have you already participated of some innovative program or research inside or outside the university? (Yes, No) Describe the positive or negative aspects of this experience.*

The sample consisted of 1290 science teachers from all six countries. Of these participants, 577 teachers (45%) answered YES, informing that they have participated in some research or innovative program. For this study we analyzed the description of these experiences and the positive and negative aspects of these experiences, only those who claimed to have participated. The data analysis was restricted to teachers who are working with science subjects at primary and/or secondary schools.

To analyze the data we have associated quantitative and qualitative approaches, to obtain results with global and particular evidences about the science teachers' perceptions of their experiences in research or innovation. Regarding the qualitative data analysis, Alves-Mazzotti and Gewandsznajder (1998, p. 170) point out that "[...] this is a complex, nonlinear process, which implies in a work of reduction, organization and interpretation of data which accompanies the entire investigation ". In the present study, we used the Discursive Textual Analysis (DTA) (Moraes & Galliazzi, 2007). The DTA method of analysis is organized around four main stages: (1) 'Unitarization', characterized by the deconstruction of texts to identify and isolate ideas. This disassembly process results in 'units of analysis', which represent "elements relating to the phenomenon which is being investigated" (Moraes, 2003, p.195). (2) Categorization, in which the units of analysis are grouped into initial categories. In the subsequent step, the initial categories are grouped in a lower number and more comprehensive categories, called intermediate categories. Finally the intermediate categories are organized in a lower number of categories. The criterion used for the categories construction is the linkage with the ideas initially fragmented. (3) 'Meta-text', in which a rigorous analysis of the categories formed gives rise to the production of different text types, called 'meta-texts', which are continuously improved resulting in the construction of the final text, and comprises the description and interpretation. (4) Communication, the last stage of DTA, in which the constructed arguments are disseminated.

Therefore, DTA is an open methodology, a process of self-organization, consisting of construction, deconstruction, rigorous analysis and data validation. The validity and reliability of the results are guaranteed by the strictness with which each analysis step of the methodology is conducted (Moraes & Galiazzi, 2007).

RESULTS

The results showed that half of the science teachers (45 %) in our sample have participated in some kind of research or innovative experience. Among those who responded affirmatively, 59% described their experiences. Table 1 shows the frequency of teachers' participations in research or innovative programs for each country of the consortium, and the number of experiences described.

Table 1 – Teachers' participation in research or innovative programs for each country.

Countries	Total sample	Participation in Research/Innovative Programs (YES)	Experiences described
Argentine	436	134 (31%)	99 (74%)
Brazil	136	66 (49%)	20 (30%)

Colombia	170	136 (80%)	108 (79%)
Israel	64	36 (56%)	15 (42%)
Italy	279	94 (34%)	14 (15%)
Spain	205	111 (54%)	82 (74%)
TOTAL	**1290**	**577 (45%)**	**338 (59%)**

Among teachers who pointed their participation in research or innovative programs, it was possible to identify different types of experiences, highly dependent on the cultural background in each country (Table 2).

Table 2 – Type of teachers' experiences in research or innovative programs.

Type of Experiences	Frequency	Percentual
Innovation programs (regional/national/public policies)	123	36.4%
Research Projects (school-university)	73	21.6%
Short-term Training Courses	39	11.5%
Long-term Training Courses	35	10.4%
Other innovative programs (interdisciplinary X disciplinary)	33	9.7%
Others (developing teaching materials, using informal environments and training offered)	35	10.4%
Total	**338**	**100.0%**

The higher frequency of teachers' experiences was on innovative programs (36,4%), which were defined in this work as those science programs proposed by public policies. This number indicates that teachers' conception of innovation are usually identified as something produced externally, and received in the school for reproduction. This top-down innovation approach use to be led by public authorities or an 'expert bringer', and teachers seem to assume a passive role in this innovative process. For example, in Argentina, a high incidence of "science fairs" experiences (30%) as a research/innovative experience was identified. Considering that this Argentinean program is part of a national policy, the results increased the first category.

The partnership model with school-university developing a research project involving groups of teachers and/or students was the second most frequent experience. In Colombia, the high score of research experience (47%) seems to indicate a strong partnership school-university or, on the other hand, a non-canonical understanding of "research or innovative programs".

Teachers also identified their participation in short and long-term teacher training as a research experience, which includes short training courses on the one hand, and master programs in the other. Finally, interdisciplinary projects involving the whole school and the production of new teaching materials were also identified as research/innovative experiences.

The positive aspects highlighted by teachers were grouped in eight categories: improvement of teaching practice (51%); contribution to increasing autonomy of teachers and students (28%); opportunities to develop peer-to-peer learning and good practices exchange (20%); teachers' reflexive thinking (18%); fitting the content to the context (18%); students' procedural and atitudinal learning

(17%); students' conceptual learning (12%); and opportunity to experience inquiry-based methodologies (11%).

Chart 1 shows some quotes of positive aspects extracted from teachers' textual answers.

Chart 1 – Distribution of positive aspects of involvement with research, by category.

Category	Quotations about the participation in innovative programs and research
Improvement of teaching practice	*"It is positive for teachers, because they can improve their practice, which reflected positively in students leaning process"* *"First, it forces you to think about your daily practice. Secondly you know what is being done on the teaching of your subject. Thirdly you can learn and improve."*
Contribution to increasing autonomy	*"The project led me to a conceptual change, my approach to students and teaching has changed significantly. By becoming a facilitator instead of a source of knowledge I learned to believe in students' ability to succeed and achieve better."* *"The positive is that encourages both the teacher and students and parents learn investigating."*
Opportunities to develop peer-to-peer learning and exchange of good practices	*"I learned from my colleagues and felt the brainstorming advanced me."* *"Understanding and exaltation of the need to work on a common science teachers' network."* *"We share with our fellows, receive advice from different people which are 'experts'."*
Improvement of teachers' reflexive thinking	*"I learned a lot from working with developers. I learned new things about myself which I haven't noticed before, and improved my teaching, as well as learned about this interesting area."* *"It is a stop on the inertial operation for rework objectives of our work."*
Fitting the content to the context	*"The positive aspect lies in the contributions that can be done not only to scientific knowledge of the country and the world, but also make contributions to the area where you work and have a defined life plan."* *"Forces the constant reflection with peers or individually on what we want our students to learn and therefore helps to better relate to them."*
Contribution to students´ procedural and attitudinal learning	*"The fact of having done research, allows us to better instill our students with the advantages of the scientific method and critical thinking in any situation."* *"It created teamwork that favored the group of students, as evidenced the need for teamwork as an important part of the educational activity."*
Opportunity to experience research methodologies	*"It is positive to place the child in contact with scientific knowledge, where they can make observations, formulate hypotheses, register and assemble their notes, draw conclusions and transmit it to others."* *"The most positive thing was the guidance in the process to raise the research problem."*

Although these positive aspects, teachers that experienced research/innovative activities complained about: lack of time and material resources (43%); lack of engagement of the school community (27.4%); lack of continuity and information about research findings (21.4%); lack of teachers training and experience in enquiry (14.2%); administrative obstacles (13.2%); and lack of connection between research and school context (9.6%).

Chart 2 shows the distribution of the negative aspects pointed out, summarized in those six main categories. Moreover, some quotes are presented as examples, extracted from teachers' textual answers, in each category.

Chart 2 – Distribution of negative aspects of involvement with research, by category.

Category	Quotations about the participation in innovative programs and research
Lack of time and material resources	*"I see that there is a lack of incentives for institutional research in the organizations, whether in budget or logistics."* *"Not rewarded or recognized school teacher we do extra work to innovate in our classrooms".*
Lack of engagement of school community	*"The negative side is the resistance from many older and experienced teachers in accepting new teaching methodologies."* *"Often people who want to do different activities or proposals, are few. Sometimes they even are viewed critically by peers. Make innovation is hard work and not always appreciated by the rest of the faculty."*
Lack of continuity and information about research findings	*"The group of teachers who are part of innovation and research programs is always the same, hardly increases."* *"It was negative due to the lack of funding and the continuity of the research program. Teachers have difficulties to leave the classroom.*
Lack of teachers training and experience in research	*"The little ownership of some teachers with the proposed methodology."* *"It would be interesting to those who work at the basic level of primary or secondary could also enjoy and have the possibility of a sabbatical year as in the universities to devote to pure research."*
Administrative obstacles	*"Requires significant time and dedication has minimal recognition by the administration."* *"The feeling that there is a great personal effort, and there is very little recognition and support for continuing by the administration. The changes require the support and the duration is long."*
Lack of connection between research and school context	*"Sometimes they are working on issues or topics that are very difficult to implement in daily practice. Also sometimes these programs are not sufficiently disclosed."* *"Trainers sometimes do not prepare us for what we found in the classroom. Should be more practical. The paper bears all, but the day to day in the classroom has some problems that are not covered from the theory."*

In teachers' opinion, the most critical negative aspect of their involvement in research/innovative programs is the lack of time and material resources. They complain about the absence of effective support from faculty and school principals, expressed by their quotations about loneliness and administrative barriers. The lack of ongoing relationship with researchers is quoted by teachers, reinforcing the importance of a stronger, closer and continuous university-school partnership. Despite teachers complain about the lack of information about research findings, they believe the contribution of research findings can transform and modify teaching practice and the positive contribution of inquiry-based approaches is extended to students' learning.

CONCLUSIONS

The results show that the most common science teachers' experiences in research/innovative programs are those mentored by public authorities/research experts and collaborative research experiences. In both experiences, research activities are predominantly led by teachers, but restricted to classroom experiences with students of each individual teacher. The collaboration between groups of teachers and students, supported by faculty members is also identified in their experiences.

The main contribution of this experience, highlighted by science teachers, is their professional development, showing the importance of introducing inquiry-based activities in pre-service teacher training, which provides a critical opportunity to bridge the gap research-teaching practice.

In the teachers' perception in all six countries, there is a lack of incentive and support for research activities as a pedagogical activity developed in schools. Teachers see the conducting of research activities as an add-on activity. The engagement and commitment of school leaders to keep research activities in their own schools should be particularly valuable to overwhelm these barriers.

There is a coherent relationship between negative and positive aspects in the research experience. They complain about the lack of engagement and support of the school community in research activities, whereas in the other side, they indicate the opportunities to develop peer-to-peer learning and exchange of good practices as positive. As a counterpoint to the lack of teacher training in research, they emphasize this experience to empower teachers in research or inquiry-based methodologies. They complain about the lack of connection between research findings and school curriculum, and from the other side, research is seen as a way to fit the school content to the context of students and/or community.

Concluding, the challenges for bridging the gap between research and practice can be related to two contexts: the school context, which should promote support for teachers engagement in research; and the academic context, which should ensure the establishment of long-term partnerships, bringing academic research close to school context and improving teacher training in research.

PATTERNS IN THE MEANING-MAKING OF SCIENCE TEACHERS INVOLVED IN A TEAM-BASED PD-PROJECT

Birgitte Lund Nielsen[1]
[1]Centre for Science Education, CSE, Aarhus University, Denmark

Abstract: The perceived outcomes of four science teachers involved in a yearlong school-based professional development (PD) project analyzing artifacts from practice in local science classrooms are examined through repeated interviews and are represented as meaning-making maps for each teacher. The teachers refer to various outcomes from the project and emphasize those parts of the project where they personally feel supported in relation to the current tensions they are experiencing in their professional work. Beside this there are similarities; all teachers refer to experiences from experiments in professional practice, and reflect on and interpret those experiences in relation to student learning. They also seem to grow to acknowledge the value of sharing practice through the facilitated collegial interactions.

Keywords: Professional development, meaning-making, in-service, professional learning, artifacts from practice

INTRODUCTION

It is acknowledged internationally that there is a need to improve science teaching, that science teachers are the key to this development and that professional development (PD) activities the teachers are engaged in can play a crucial role (e.g. Feinam-Nemser, 2001). In Denmark a number of science teachers have been educated to diploma level in recent years and act as resource teachers within their schools to support PD. However PD for most science teachers is still short, out-of-school courses detached from practice in spite of a growing consensus on the most beneficial approaches to teachers' PD. It appears that PD gains from being school based, focused on student learning, long term, content focused, and collaborative, and from incorporating inquiries into practice (Roth, 2007; Borko, 2004). The sharing of classroom videos in video clubs has been reported to produce a focus shift towards student learning (Sherin and Han, 2004), and there is a growing acknowledgment of the role played by cooperation among colleagues, teacher learning communities, with respect to an individual teacher's learning (McLaughlin and Talbert, 2006).

Teachers' professional learning can be seen as a change in knowledge and beliefs and/or a change in teaching practice (Bakkenes, Vermunt, and Wubbels, 2010; Borko, 2004). With a socio-cultural perspective acknowledged, and with the knowing and learning of teachers seen as constructed through participation in different aspects of local practice and discourse (Borko, 2004; Edwards 2001) research must seek an understanding of the teachers' experiences, how they make sense. The term meaning-making has been used for two decades in part of the research into students' learning in science classrooms (Abell, 1992; Mortimer and Scott, 2003). Meaning-making can when discussing (science) teachers' professional learning be conceptualized as a fine-grained perspective on their on-going construction of understanding and interpretation of experience in a particular setting or context.

The interconnected model of teachers' professional growth (Clarke and Hollingsworth, 2002) suggests that teacher learning occurs through the mediating processes of reflection and enactment connecting four distinct domains (situated in the change environment), namely:

- External domain: information, stimulus, and support from external sources;
- Domain of practice: professional experimentation in the classroom;
- Personal domain: teacher's knowledge, beliefs, and attitudes;
- Domain of consequence: salient outcomes.

Collegial interaction is part of the change environment surrounding all the domains, but in other studies collegial interactions are seen as the main field of interest in the domain of consequence (Van Driel and Beijaard, 2003). With learning communities as the focus for much contemporary debate and research more knowledge on collegial interactions is surely needed. However, empirical research looking into the individual teacher's professional learning in collaborative settings is lacking: knowledge regarding teachers' process of developing ideas and understanding while participating in learning communities, how they make use of inputs and how they engage in professional experimentation.

RESEARCH QUESTIONS

In the context of a collaborative project that uses artifacts from practice in local classrooms to focus on students' thinking and learning in science, the research questions are:

1. How do individual teachers reflect on the project?
    a) What outcomes do they identify?
    b) To which aspects of the project do they refer?
2. What links do the teachers make between a) and b), and what insight into their meaning-making do these provide?

THE LOCAL PD-PROJECT

The local PD project being the frame for this research is situated at a school that offers primary and lower secondary-level: grades 1 to 6 are taught integrated Science & Technology, while grades 7 to 9 have separate lessons for Biology, Geography, and Physics & Chemistry. All teachers who teach on of those science subjects are in the science team. Interviews before start of the project indicated considerable variation in the teachers' engagement in cooperation in the team and in developing science teaching locally. The idea to use artifacts from practice, in particular classroom video, to focus on students' learning in science, was presented by the facilitator (and researcher), but the project was situated at the local school and the particular themes raised were decided in the team. Facilitated experimentation with new tools and the collection of video data and other artifacts took during the yearlong project place between a range of half day workshops. Examples of collected artifacts and the work in the workshops are referred to below. The facilitator structured the discussions during the workshops and, when needed, offered input and tools from the knowledge base of research in science education regarding typical student preconceptions and alternative conceptions in science.

METHODOLOGY

Data were collected through semi-structured interviews. Interviews with participating teachers and the school pedagogical leader before workshop 1 were used to collect background data. Four teachers were then selected for an in-depth study focused on the teacher's science teaching during the project period and the PD experience. Purposive sampling was used to represent different levels of experience and teaching across a range of grades (Cohen et al., 2007). The four teachers were:

- Teacher A: novice teacher in her first year of teaching science, specialized in Science & Technology, teaching Science & Technology in 5th grade.
- Teacher B: in her third year of teaching, specialized in Geography, a non-specialist teaching Science & Technology across all 3rd grade classes.
- Teacher C: an experienced teacher specialized in Biology, teaching Science & Technology in 6th grade, has recently taken a diploma degree in Science Education acting as resource teacher for the science team.
- Teacher D: the most experienced/senior teacher, specialized in Geography, teaching 8th grade Geography.

The interconnected model (Clarke and Hollingsworth, 2002) was adapted as analytical model to facilitate analysis and representation of the complex interplays in relation to the teachers' meaning-making. The model was adapted with a new *domain of collaboration* to include the collegial interactions facilitated during the project (Van Driel and Beijaard, 2003) (Fig. 1).

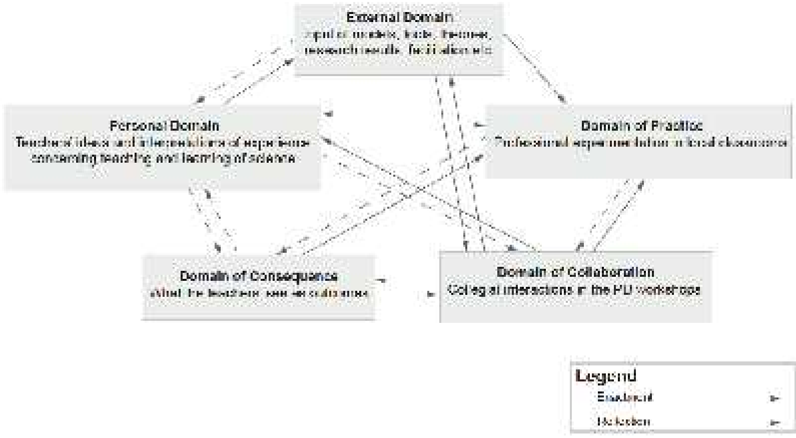

Fig. 1. Meaning-making model

The domains in the model are linked by the arrows reflection and enactment to represent how change in one domain is translated into change in another. When a teacher's reflection involves two domains, a reflection arrow is used between the domains; when the teacher refers to how something in one domain entails something in another domain, an enactment arrow is used. The final representation is called a meaning-making map. Clarke and Hollingsworth (2002) alternate between calling the illustrations change sequences and growth networks when interpreted as more lasting growth. The naming used here emphasizes the research aim: to examine teachers' perceived outcomes and represent their meaning-making.

In the first step of analysis interview transcripts were analyzed to identify utterances relating to each individual domain. In the second step utterances categorized as belonging to more than one domain in the first step were identified and the domains linked by reflection or enactment. For example, when asked about outcomes teacher B refers to her experience of teaching unfamiliar science content: "I think it has been really good teaching this electricity [..] while they simply loved to go to the science-lab and to do those experiments". The teacher reflects on something she sees as an outcome (domain of consequence) and links it to something new she has tried in her class (domain of practice), so a reflective arrow is made. Teacher B continues talking about this, saying that "in discussions in class [..] you could follow how various students [..] caught the point". A reflective arrow between the domain of practice and the personal domain represents her interpretation of experience in relation to students as learners. When referring to her professional work looking forward, she says she wants "to try new approaches in my class, like the one we tried with electricity". An enactment arrow from the domain of consequence to the domain of practice, represents an intention to build on this outcome through further professional experimentation.

The third step of analysis was a process of constant comparison to develop open coding categories that described the content of the of teachers' utterances referring to each domain.

FINDINGS

Findings will be presented as a meaning-making map and a pen-portrait for each teacher.

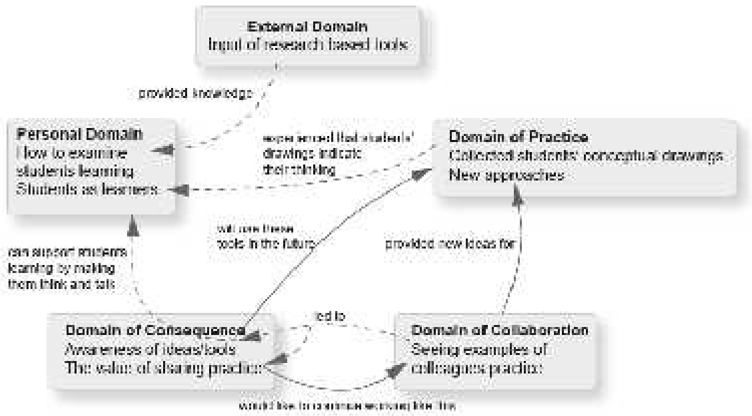

Fig. 2. Meaning-making map teacher A

Domain of collaboration can be seen as a key domain to understand teacher A’s meaning-making (fig. 2). The inspiration from colleagues is what she emphasizes as the main outcome. She refers to discussions about students’ thinking based on video from colleagues’ practice and how she became aware of the benefit of using tools like concept cartoons (Keogh and Naylor, 1999). Her emphasis on students talking science is developed along the project. In the first interview she focused very much on hands on activities as an ideal, but she also referred to having problems with classroom management sometimes letting the students do written work instead of experiments. In the second interview her emphasis is more on letting students think and talk than on activities in it-self. During the project she collected drawn and written artifacts to examine her 5th grade students’ understanding of cardiopulmonary circulation (Domain of practice). The students were asked to draw, in a pre-drawn shading of a body, the processes and functions of human blood circulation, following some lessons in physiology, where they, among other things, dissected the hearts of pigs. The drawings were discussed in on of the workshops. She did not refer to this in the retrospective interview until she was prompted, following her spontaneous reference to what was seen in her colleagues’ classrooms. However, when asked what she gained from this experience she reflected on and interpreted the students’ drawings, saying “it is clear that they draw the heart and not the lungs […] getting the lungs in and the two circuits, it was hard for them”. She also noticed that the students had a tendency to draw one-way blood circulation out from the heart.

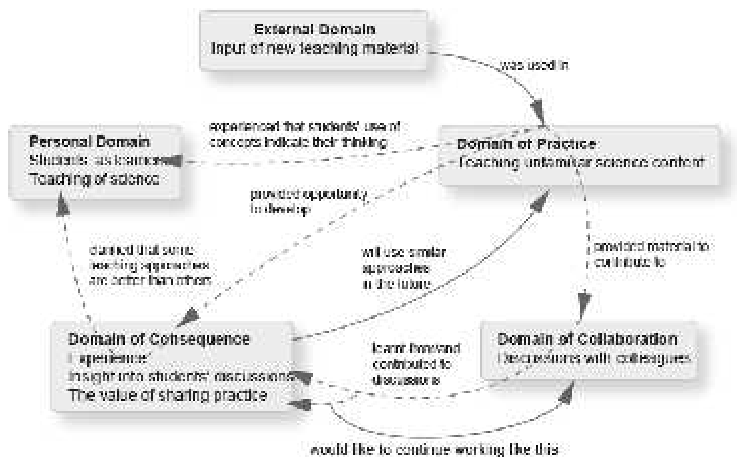

Fig. 3. Meaning-making map teacher B

Teacher B taught electrical circuits for the first time during the project (fig 3). In the interview she refers to the teaching material that involved continuing shifts between students posing hypotheses, their progressing experiments, and class and group discussions. Various artifacts from her 3rd graders, including video, were discussed in the workshops. Preconceptions from many 3rd graders were identified in relation to only one connection needed from bulb to battery or two ‘arrows’ from the battery meeting in the bulb. After a few lessons all the students referred to circuits and most students specifically attached the wire to two different places on the bulb. The domain of practice can be seen as the key domain in teacher B’s meaning-making map. Nearly all reflections are connected to this positive experience. It seems to have clarified for her that some teaching approaches are better than others. Referring back to an earlier experience at a local resource center, she states that too much emphasis was on ‘science as a show’ compared with the focus on students’ thinking used now. Teacher B also refers to presenting video and other artifacts from her classes in the team. In retrospect, she sees herself as having been passive in the science team before “I didn’t feel it was my field, I do not have very much physics*”,* but she values being able to contribute in the project.

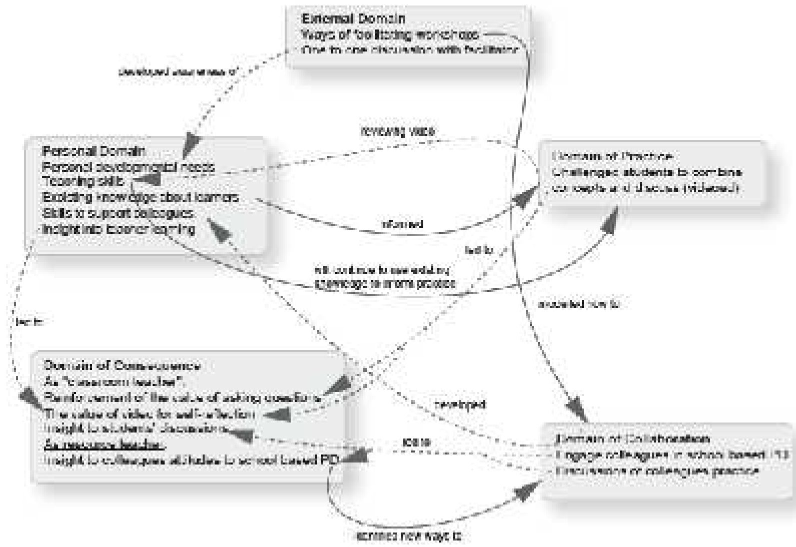

Fig. 4. Meaning-making map teacher C

Teacher C has the most complicated map (fig. 4) as nearly all her considerations involved reflections from being both a resource teacher and a classroom teacher. Her teaching in two 6th grade classes involved examining students’ preconceptions and their experiments with simple chemical analysis. The emphasis in the material she used was on the systematic approach, and before doing experiments the students discussed in groups what a criterion is and what classification is. As a resource teacher, she wanted more colleagues to be aware of this approach that she knew from her diploma. She backs her teaching on her existing knowledge about students as learners. Reviewing video informed her own practice; she mentions the value of asking questions instead of just giving answers. The project also informed her as a resource teacher, providing insight into her colleagues’ practice. She reflects on how you “learn as a teacher by seeing/doing it yourself, not just by being told”. In that way the domain of collaboration can be seen as another domain of practice for her. Being a resource teacher can be challenging, and teacher C through the project developed an awareness of personal developmental needs. She refers to one-to-one discussions with the facilitator and to being inspired by the way the workshops were facilitated: “It is good to get this from outside, so I also feel that I get some ‘feedback and support’ [she uses the term “sparring”]*”.*

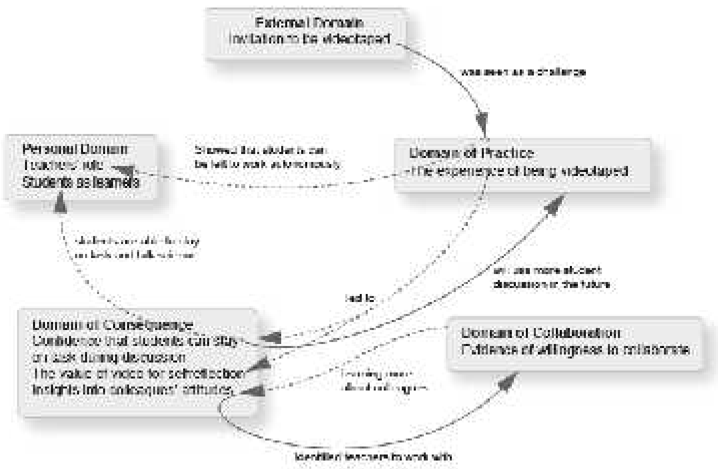

Fig. 5. Meaning-making map teacher D

During the project teacher D tried a tool inspired by concept cartoons to encourage 8th graders' to discuss the earth's climate. The students in groups discussed three suggestions by named imaginary young people. The 8th graders were very engaged in the discussion, contrary to what teacher D had expected; she had thought before the lesson that this was 'a piece of cake', as the theme had been taught in 7th grade. In a workshop the students' misconceptions, such as distance from the earth as an aspect rather than tilt and angle of incidence, were identified. The video and post-lesson essays from the students revealed how they, through discussion and purposeful questioning from teacher D, developed largely scientifically correct explanations, expressed in their own words. Teacher D's meaning-making map looks very much like teacher B's, but the experience of being videotaped per se is her focus. She does not mention presentation and discussions of video from her class in the workshops as teacher B does; it is her own self-reflection based on the video that she sees as an outcome. She refers to the science team as individuals pulling in various directions, and emphasizes the lack of cooperation between lower secondary science teachers. The project, however, has provided her with evidence of some colleagues' willingness to collaborate.

DISCUSSION

Teacher A's expressed idea about active self-regulated students seems to create a tension in relation to her coping with classroom management and so does her expressed wish to be able to answer all the students' questions, as she does not feel confident in physics. Novices struggling with classroom management, their activity orientation and low efficacy beliefs in the area of physics, which is also expressed by teacher B, are general challenges among Danish science teachers (Nielsen, 2011). In relation to A's meaning-making the interesting issue is that through her journey in the project she seemed to be in a development. She emphasizes inspiration from colleagues, which help her in the area of tension providing tools to see science as more than students' hands-on activities. Artifacts shared in collegial interactions seem to give her some event-structured knowledge to help see how the input from facilitator and colleagues can be used in concrete classroom situations. It might be that this way she gets ideas and efficacy to experiment more purposefully in her own practice. Teacher B's meaning-making map, her outcomes from experimenting with new approaches, can be seen as a general pattern. It has a close resemblance to patterns in teachers' learning mentioned in previous studies (e.g. Bakkenes et al., 2010). Teacher D's map shows nearly the same pattern and all four maps have reflective arrows between the domain of practice and the personal domain. In spite of local barriers there seems to be a growing awareness among the teachers of how they gain from collaboration for example teacher B when facilitated in developing her own practice seems to feel she has something to contribute to the team and when this is successful she gains even more confidence.

CONCLUSIONS AND IMPLICATIONS

The four informants emphasize various outcomes from the project; they seem to follow individual trajectories and in retrospect to identify outcomes connected to current tensions in their professional work. However all the teachers refer to their experiences from experiments in professional practice and reflect on and interpret those experiences in relations to the students' learning of science. In relation to implications for the design of PD, school-based projects give the opportunity for local experiments being shared collaboratively and such facilitated collegial interactions might be needed to acknowledge the value of sharing practice. This might lead to a continual effort to qualify local practice: potential generative development. School-based PD also serves the possibility to acknowledge individual tensions, which in this study has shown to be determent in relation to their professional learning.

TEACHERS AS *LEARNERS* AND *DESIGNERS* OF ICT-DRIVEN SCIENCE CURRICULUM MATERIALS: FINDINGS FROM THE "ICT FOR INNOVATIVE SCIENCE TEACHERS" PROJECT

Marios Papaevripidou[1], Michalis Lividjis[1], and Costas P. Constantinou[1]
[1]Learning in Science Group, University of Cyprus

Abstract: The purpose of this study was to examine the influence of a professional development course on teachers' evolved understandings of the ways ICT tools could be integrated in science teaching to scaffold and facilitate the learning process. The participants were nine physics teachers enrolled in 7 two-hour sessions that made use of two ICT tools. The course was organized in two phases. During Phase 1 ("teachers as *learners*"), the teachers were engaged in multiple cycles of data collection and analysis (through data sensing and logging), modeling (e.g., building, refining, testing, and validating models), video analysis, and investigation through the use of simulations. During Phase 2 ("teachers as *designers*"), the teachers re-designed an existing unit from their science curriculum to foster the development of understanding of the unit's concepts through the use of ICT tools. Data sources included teachers' responses to a written pre/post questionnaire about their prior teaching experiences with ICT, reflective diaries and teachers' lesson and unit designs. The findings revealed that the participants expanded their understandings of the various ways that ICT tools can be integrated within science instruction and they also shifted from the "authoritarian" model that dominated the majority of their initial designs to a more student centered approach through which the students use ICT tools for sense making, exploration, and knowledge construction. Additionally, modeling activities were very limited within teachers' revised lesson designs or totally omitted from their reconstructed units, a finding that points to teachers' inadequacy to develop epistemic awareness with respect to the purpose and the role of models and modeling in science teaching and learning. The paper concludes with a discussion of the relevant professional development issues and a set of recommendations about the underpinnings of ICT professional development courses.

Keywords: teacher professional development, ICT-enhanced teaching and learning, teacher understanding of ICT usage

THEORETICAL BACKGROUND

Although reform documents call for the integration of ICT tools in science teaching, it has been reported that teachers appear to have difficulty with creating classroom environments in which students are supported in creating their own constructions of knowledge through the use of ICT tools (Koehler, Mishra, & Yahya, 2007). A major factor that contributes to teachers' struggles with integrating technology into their teaching in a constructivist way relates to the absence of a theoretical framework from training seminars or professional development programs that guides the nature of technology integration into teacher learning (Hughes, 2004). As a result, ICT courses and workshops frequently tend to focus on providing teachers with technical skills necessary for operating the hardware and software (Kennewell, 2001; Zhao et al., 2002), and leave aside the pedagogical underpinnings behind the technological integration in science teaching and learning.

If we anticipate from teachers to become "technology integrationists" (Hughes, 2004), then teacher professional growth programs should aim to "… change teachers to teachers as active learners [by] shaping their professional growth through reflective participation in professional development programs and in practice" (Clarke & Hollingsworth, 2002, p. 948). Advocates of the *teacher as learner* approach emphasized the importance of designing professional development courses through which teachers should be offered "...opportunities for learning from teaching, rather than learning of teaching" (de Jong, van Driel & Verloop, 2005, p. 6). This *teacher as learner* approach moves beyond the traditional teacher preparation tradition through which teachers learn how to write good lesson plans or act as (passive) receivers of information about the various strategies of how to teach, as it places the teacher directly in the role of inquirer in simulated research experiences.

It is also equivalently important to give teachers the authority to act as designers of their own ICT-driven science curriculum materials, because engaging teachers in constructing a public artifact (e.g., their own curriculum) is a productive way to support their learning (Papert, 1991) and the transformation of their personal learning experiences into pedagogically potent curriculum designs. Teachers should take the role of active participants in any implementation or instructional reform we seek to achieve, and thus we need to offer them a certain degree of autonomy and power in making pedagogical decisions while designing and implementing their own curriculum (Mishra & Koehler, 2006). The idea of *teachers as curriculum designers* is based on the stance that teachers are "an integral part of the curriculum constructed and enacted in classrooms" (Clandinin & Connelly, 1992 p. 363), since their effort of curriculum development undergoes an organic process of iterative design, refinement and negotiation of a balance between technology, pedagogy, and content (Mishra & Koehler, 2006).

PURPOSE AND RESEARCH QUESTIONS

Grounded on the tenets of the teacher as *learner* and *curriculum designer* perspective described above, the purpose of this study was to examine the influence of a Professional Development Course (PDC) on the development of teachers' informed understandings about the various ways that ICT tools could be integrated in science teaching to scaffold and facilitate the learning process. Specifically, the two research questions that this study aimed to address were as follows: (1) *What did teachers' learn in terms of (i) how ICT tools are integrated in science teaching and (ii) the role of ICT tools in science teaching, as a result of their participation in the PDC?*; and (2) *How did teachers' ICT-driven lesson designs change as a result of their participation in the PDC?*

METHODS

Participants and Setting

The participants were nine physics teachers (7 males, 2 females) enrolled in a Professional Development science education Course (henceforth called PDC) that made use of two types of software, namely "Data-logging Insight" and "Coach 6". Five of them held a master degree in physics and all of them were at the time carrying a full teaching load. None of them had participated before in a course on how ICT can be integrated within science instruction.

The course was organized in two consecutive phases. During Phase 1 ("teachers as *learners*"), curriculum materials that were developed in the contexts of "Change of State" and "Forces and Motion" were implemented through which teachers were engaged in multiple cycles of data collection (through data sensing and logging), data analysis, modeling (e.g., building, refining, testing, and validating models), video analysis, and investigation through the use of simulations. After every session, the participants were asked to write reflective journals about their experiences and knowledge gained about the use of ICT tools in each session. During Phase 2 ("teachers as *designers* of ICT- driven curriculum materials"), the teachers were asked to reconstruct a unit from the school curriculum to foster the development of understanding of the unit's concepts through the use of ICT tools. As part of the requirements for their curriculum designs, teachers were asked to: (i) formulate learning objectives, (ii) provide descriptions of the design and the implementation of each activity, (iii) design activity sheets based on their activities' descriptions, and (v) design assessment tasks to evaluate their learning objectives.

Data collection and analysis

We collected multiple forms of data throughout the course; (i) teachers' responses to a written questionnaire about their beliefs and attitudes concerning the role of ICT in their teaching, and their knowledge and prior experiences regarding the use of data logging, modeling and video measurement software tools; (ii) teachers' initial and revised lesson designs that illustrate the use and role of ICT tools; (iii) teachers' reflective journals; and (iv) teachers' reconstructed units. The data were analyzed quantitatively using descriptive statistics and qualitatively using an open coding scheme refined through the use of the constant comparative method (Glaser & Strauss, 1967).

FINDINGS

What did teachers' learn in terms of (i) how ICT tools are integrated in science teaching and (ii) the role of ICT tools in science teaching, as a result of their participation in the PDC?

The analysis of the data collected from questionnaires that were administered at the beginning of the course, revealed that the participants had a very limited understanding of the ways that ICT tools can be integrated within science instruction to facilitate the learning process, as they stated that the teacher was the one that makes use of ICT tools and the ICT tools were used mostly for demonstration purposes within a science lesson. Evidence from teachers' reflective diaries during the course indicates that the types of activities that they were engaged with enabled them to expand their understanding of the various ways that ICT tools can be integrated within science instruction and they also appeared to have appreciated the multiple learning benefits from such integration. Specifically, the majority of teachers reported that throughout the course they learned how to analyse data with the use of specific software, identified advantages of the use of ICT in relation to the collection of more accurate measurements and performance of easier and faster data analysis, and appreciated the role of ICT in promoting students' interest towards science.

Apart from evaluating teachers' learning about the use, the role and contribution of ICT tools in relation to teaching and learning, we also examined teachers' evolved understandings about models and modeling, since they were engaged with modeling activities within the PDC. We summarize the findings from teachers' understanding of the nature of models and modeling in Tables 1 and 2 respectively.

Table 1. Teachers' understanding of the nature of models prior to and after the PDC

Category of response	Prior to the PDC	After the PDC
A model is …		
…a mathematical expression of a theory	1	-
…a specific environment for simulating or studying a phenomenon	1	3
…a construct (e.g., an apparatus, an algorithm) that we use to study a phenomenon	2	-
I don't know this term	5	-

...a set of mathematical equations that strengthen the description of a phenomenon	-	2
... is a program that runs on the computer and substitutes the experimental procedure. It produces error-free measurements and hence it helps in our understanding of the natural phenomenon	-	2
... the representation of a phenomenon with the use of a software. It needs to represent the phenomenon under study, provide a mechanism that explains how the phenomenon functions, and enable the formulation and testing of predictions	-	2

Table 2. Teachers' understanding of the nature of modeling prior to and after the PDC

Category of response	Prior to the PDC	After the PDC
Modeling is …		
..the simulation of natural phenomena in a specific environment	3	2
..a number of equations through which natural states are simulated in a way that information of how a phenomenon functions can be achieved	2	-
.. ..the process through which our understanding about how a phenomenon functions is represented in a model	1	1
..the use of a model from a theory to study a phenomenon	1	1
..the creation of a standard frame for studying a phenomenon	1	
..the creation of an artificial environment (or a simulation) for studying a phenomenon	1	4
..the creation of a model after observing a phenomenon. Next, the model can be improved through comparing it with the physical phenomenon. The model needs to represent the phenomenon and enable the testing of predictions. In case the model fails to fulfill these criteria, we need to return to the initial stage of modeling and revise the model accordingly	-	1

The findings reported in Tables 1 and 2 indicate that the participating teachers failed in making a substantial shift from their naïve conceptions expressed prior to the PDC to more sophisticated understandings of the nature of models and modeling. Although prior to the PDC the majority of the teachers were unfamiliar with the concept of "model", after the PDC seemed to have associated this concept with the software that was used for creating a model or simulating a phenomenon. In other words, they appeared to have conceived the models as technical tools and not as representational tools that facilitate our understanding about the underlying mechanisms of the phenomena being modelled. Likewise, the majority of the teachers after the PDC stated that modeling concerns the creation of an artificial environment or a simulation, a view that demonstrates their failure to conceive modeling as a process of developing and deploying models that account to our observations and serve as means to facilitate our understanding of a phenomenon.

How did teachers' ICT-driven lesson designs change as a result of their participation in the PDC?

The analysis of teachers' initial and revised lesson designs and the unit that they reconstructed was centered around the types of ICT that teachers chose to incorporate within their lesson designs, the role of the ICT tools in relation to the teaching and learning and the ways that the ICT tools were used to scaffold the learning process. We summarize the findings from this analysis in Table 3.

Table 3. Types of ICT tools and ICT-driven activities within teachers' initial and revised lesson designs and reconstructed unit

	Type of ICT-driven activity	Prevalence of each type of activity within the … initial lesson design	revised lesson design	unit reconstruction
1.	The teacher uses videos for demonstration purposes at the beginning of lesson to stimulate students' interest	4	3	2
2.	The teacher presents pictures through a projector connected to a computer at the beginning of the lesson to stimulate students' interest	3	0	1
3.	The teacher shows a simulation of a phenomenon under study to the students	3	5	2
4.	The teacher uses sensors to collect data from an experiment s/he performs	3	0	1
5.	The teacher presents graphs developed in a software of the data collected from an experiment	1	0	0
6.	The students work in groups and use ICT for data logging and data analysis	2	7	8
7.	The students work in groups and investigate a phenomenon through a simulation	0	2	2
8.	The students work in groups and use a modeling tool to construct a model of a phenomenon under study	0	2	0
9.	The students work in groups and use a video analysis software of a phenomenon under study	0	1	1

The findings reported in Table 3 indicate that at the beginning of the course the majority of teachers chose the use of ICT for demonstration purposes (see types of activities 1, 2 and 5 in Table 3). Even in the case of integration of a simulation within the initial lesson design (see type of activity 3 in Table 3), the way that the simulation was suggested for use was again for demonstration purposes and not for the investigation of a phenomenon through the manipulation of the variables of the simulation. This type of ICT use was consistent with teachers' prior experiences and knowledge that were reported in the questionnaire prior to the PDC and presented in the previous section of the Findings.

Another interesting finding that was revealed from the data collected for answering the second research question and merits attention relates to "who" will be using the ICT tools during the implementation of the lesson design. All but two teachers described that they themselves would use the ICT tools and not the students. Hence, we might assume that the teachers prior to the PDC felt that either the ICT is a powerful tool that is used only by the teacher who is willing to make her instruction more interesting and compelling or that their students would not be able to use the ICT tools appropriately due to lack of skills on how to use them or that the ICT tools could not be used as learning tools to enhance students conceptual understanding or the development of reasoning skills.

Evidence from the analysis of teachers' revised lesson designs and the unit that they reconstructed revealed that, after the course, the teachers shifted from the "authoritarian" model that dominated the majority of their initial designs to a more student-centered approach (see types of activities 6 through 9 in Table 3) through which the students use ICT tools for sense making, exploration, and knowledge construction. Specifically, after the course the majority of teachers suggested that they would organize their students to work in groups and they would let their students to use the ICT for data logging and data analysis.

However, modeling activities were very limited within teachers' revised lesson designs or totally omitted from their reconstructed units, although they engaged in several modeling activities during the PDC. A possible explanation that accounts for this failure might relate to teachers' inadequacy to develop epistemic awareness with respect to the purpose and the role of models and modeling in science teaching and learning, as it has already reported in the findings presented for research question 1.

CONCLUSIONS AND IMPLICATIONS

In this study we aimed to explore whether a Professional Development Course (PDC) that builds upon the premises of teachers as *learners* (Clarke & Hollingsworth, 2002; de Jong, van Driel & Verloop, 2005) and teachers as *curriculum designers* (Mishra & Coehler, 2002) could impact on the development of teachers' informed understandings about the various ways that ICT tools could be integrated in science teaching to scaffold and facilitate the learning process. The findings revealed that during the PDC the participants expanded their understandings of the various ways that ICT tools can be integrated within science instruction and they also shifted from the "authoritarian" model that dominated the majority of their initial designs to a more student centered approach through which the students use ICT tools for sense making, exploration, and knowledge construction. We believe that by allowing teachers to design their own curriculum materials, we offered them opportunities to think of issues like "How does ICT-driven instruction look like in practice?" or "What do I expect from my students to develop during their engagement with ICT-driven activities?" Hence, we argue that without teachers' personal involvement in developing these materials, the understanding of the role of ICT tools in science teaching and learning, to the extent that appeared to occur because of their personal involvement, would not be possible.

However, the participating teachers seemed to have not developed informed understandings about the nature and the role of models and modeling since the modeling activities were limited within teachers' revised lesson designs or totally omitted from their reconstructed units. A possible explanation that accounts for this failure might relate to teachers' inadequacy to develop epistemic awareness with respect to the purpose and the role of models and modeling in science teaching and learning. This finding is in line with what Justi and van Driel (2005) found in their study, as they reported that even though teachers received information about how to integrate modeling principles in their science instruction, they were neither became committed to such approaches nor felt that their instruction would be more effective and productive by applying them. Consequently, we suggest two important revisions/additions to the format of our PDC in order to succeed on helping teachers to design and implement modeling-based activities for their future implementations. We elaborate on these suggestions in the following sections.

The first revision we would like to suggest relates to the design of extra activities during the first phase of our PDC (Teachers as Learners) that would engage the participants in more explicit epistemological discourse about models and modeling. For instance, after the teachers develop a model about a phenomenon they observe, it is important to prompt them to reflect on (i) the procedure they followed for developing their model (e.g, did they follow a linear procedure or a cyclical one? what were the several phases they went through for developing their model and what did they do during each phase?), (ii) the nature of their model (e.g., what aspects from the phenomenon are represented within their model and why did they choose these aspects to incorporate to their model), (iii) the criteria they should use for evaluating their model (e.g., representational coherence, explanatory power, and predictability), (iv) the role of creating models within science instruction and in science in general. By engaging teachers in the abovementioned epistemologically oriented activities, we expect that the teachers will develop epistemological awareness about models and modeling and thus they would think of similar activities when whey will design their own curriculum materials.

The second and more major revision we suggest concerns the addition of an intermediate phase between Phase 1 (Teachers as Learners) and Phase 2 (Teachers as Curriculum Designers) through which teachers as curriculum thinkers this time, would engage in several reflective activities through which they will be given the opportunity to view and analyse ICT-driven curriculum materials from a pedagogical and instructional perspective. For instance, we propose that this new phase would engage teachers in the study of the underlying pedagogical and technological underpinnings of the curriculum that were engaged with during acting as learners or other ICT-driven curricula. Several prompts for reflection (e.g., *What learning objectives are promoted through each activity? How the development of conceptual understanding is promoted in the curriculum? What is the role and contribution of a specific ICT tool in the curriculum? What is the added value that the ICT tools bring in the curriculum?*) would be added in order to scaffold teachers' thinking. Some representative reflective prompts are as follows:

In summary, we conjecture that any professional development course that aims to help teachers to become effective technology "integrationists" should give emphasis on the development of their ability to (i) understand, consider, and choose to use technologies only when they uniquely enhance the curriculum, instruction, and students' learning, and (ii) to interpret new technology concepts through their professional knowledge – the knowledge that both consciously and subconsciously directs their daily teaching activities (Hughes, 2004). As a result, teachers are anticipated to use their general pedagogical knowledge, subject matter knowledge, and pedagogical content knowledge (Shulman, 1987) to identify promising, innovative ways that technologies may be used to teach their subject area (Margerum-Leys & Marx, 2002).

PRE-SERVICE PHYSICS TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE IN DIFFERENT TEACHER EDUCATION PROGRAMS

Josef Riese[1], Christoph Vogelsang[2] and Peter Reinhold[3]
[1]Universität Paderborn, Germany
[2]Universität Paderborn, Germany
[3]Universität Paderborn, Germany

Abstract: The current discussion about the reorganization of teacher education programs resulted in a rising interest in (physics-) teachers' professional knowledge. This field, however, lacks empirical research concerning the professional development within the university part of teacher education programs. Against this background, a paper-and-pencil-test was developed to measure different aspects of professional competence including pedagogical content knowledge (PCK). Based on a measurement of competence in a group of 430 students in lower and upper secondary level teacher education programs, our study compares those different programs in order to determine their efficacy. Furthermore, our study presents results concerning the development of physics student teachers' PCK and its interplay with other domains of professional competence. In this context, the duration of the education, the amount of CK and the final school exam grade were identified as relevant predictors of students' PCK. Additionally, conclusions are drawn concerning the validity of the test approach. Apart from several pilot studies, a specific study is conducted to validate the paper-and-pencil-test regarding beginning teachers' action competence. Therefore a video based instrument was developed to measure science teachers' quality of performance in real classroom situations.
Key words: PCK, teacher education, professional competence, physics

PROBLEM DEFINITION

In recent years, unexpected and disappointing results of large scale assessments like PISA and TIMSS have led to a broad discussion about reasons and necessary changes of science education in Germany. The assumption that science teachers do not acquire sufficient competencies and skills for "high quality" instruction within their teacher education programs causes a rising interest in what are important aspects of – especially physics – teachers' professional competencies and in how these are implemented in education programs. Despite of many interesting approaches and projects, there is still a lack of empirical research findings concerning these questions. Up to now it is unclear to which extent needed competencies and skills are acquired and what their development is like especially in the pre-service phase of teacher education.

In the area of Physics, this study exemplarily shows a possible procedure how to operationalize pre-service teachers' pedagogical content knowledge (PCK) and how to develop corresponding instruments according to theoretical principles. Furthermore, a specific study is conducted to validate the paper-and-pencil-test regarding trainee teachers' action competence. Therefore a video based instrument was developed to measure science teachers' quality of acting in real classroom situations.

Physics Teacher Education in Germany

German teacher education programs are highly variable between different federal states. Nevertheless they have a common general structure. A first academic phase of teacher education with a duration of three or four years is followed by a one to two years lasting practical phase of in-service teacher training. In most federal states there are two different physics teacher education programs for secondary level schools, which emphasize different aspects of science instruction according to different school types and mainly vary in the "depth" of the implemented content knowledge in physics. According to this, differences concerning the acquired competencies in these two education programs can be expected.

Objectives

To get findings regarding the outcomes of different physics teacher education programs, this study aims on three main objectives. First (1) a model of pre-service teachers' professional action competence has to be conceptualized. In a second step (2), a quantitative instrument to measure different aspects of this competence has to be developed, piloted and validated, which can be used to analyze (3) the development of pre-service physics teachers' professional action competence in lower and upper secondary level teacher education programs.

THEORETICAL FRAMEWORK

Professional Action Competence

Summarizing the findings in the domain of investigating the efficacy of teacher training, Baumert & Kunter (2006) developed a heuristic model of professional action competence (fig. 1).

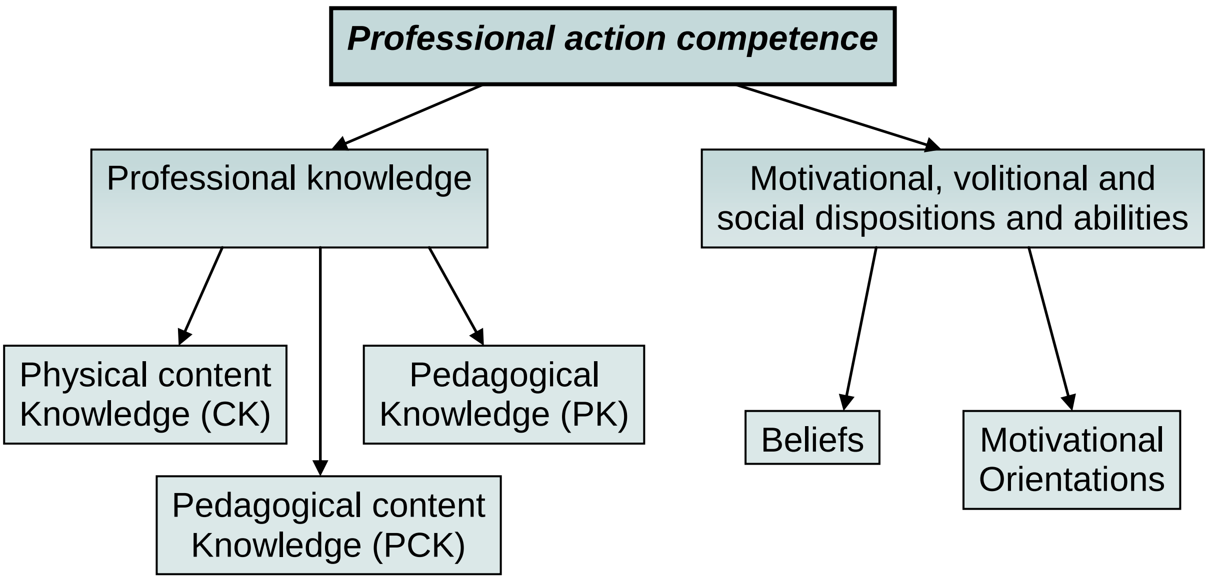

Figure 1 "Heuristic model of teachers' professional action competence"

At the core, the model draws on Weinert‘s (2001) conceptual classification of the concept of competence to characterize the structure and development of teachers’ professional competence. Thus, competencies refer to necessary prerequisites that have to be available for successfully meeting complex demands in a specific domain. Against this background, one aspect of professional competence reported in the literature is professional knowledge. According to a classification established by Shulman (1986) and widened by Bromme (1992), three aspects of teachers’ professional knowledge can be identified: content knowledge (CK), pedagogical content knowledge (PCK) and pedagogic-psychological knowledge (PK). Furthermore, it has to be considered that professional action competence, beside theoretical skills and knowledge, also comprises practical skills and knowledge up to the development of patterns of acting (Fenstermacher, 1994). Although there are further components of teachers’ professional competence like beliefs and personality factors (Jones & Carter, 2007), this article concentrates on the operationalization of PCK.

Pedagogical Content Knowledge

Shulman defines pedagogical content knowledge as a specific type of knowledge of professionals in the field of teaching and includes “the most useful forms of presentation of contents, the most powerful analogies, illustrations, examples, explanations and demonstrations […], the way of representing and formulating a subject that make it comprehensible to others” (Shulman, 1986, p.9f). Besides several other aspects, PCK also includes knowledge about typical difficulties in teaching a specific topic and especially students pre- and misconceptions. Shulmans’ concept of PCK formulated a base for various research projects in the field of teacher education and therefore was often widened, reconceptualized or adopted in many different ways. According to Lee & Luft (2008), the following dimensions of PCK can be formulated: subject matter, representation and instructional strategies, student learning and conceptions, general pedagogy, curriculum and media, context, purpose and assessment. To investigate education programs for pre-service physics teachers, these aspects of PCK have to be concretized according to the domain of physics.

OPERATIONALIZATION OF PCK

Because of limited time while surveying those differentl aspects of pre-servive physics teachers’ competence, there is a focus on the role of experiments as a specific type of physics instruction on the one hand and student misconceptions regarding the domain of mechanics on the other hand. The former decision is well-founded due to the importance of experiments in physics instruction. It has been observed that about 60 % time of a normal German physics lesson is related to experimenting (Tesch, 2005).

To make sure that all relevant aspects of competence are represented by tasks within the developed instrument, a framework of PCK in the domain of physics was designed while using normative models in terms of teaching physics on the one hand and observations of instructing-practice (e.g. best-practice-examples in video-based studies) on the other hand. So a best possible practice, based on teaching-related demands, is our starting-point. By applying these findings, the following relevant facets were identified: Knowledge about general aspects of learning physics, knowledge about a proper use of experiments, arrangements of learning processes, assessment and reflection of learning processes and finally an adequate reaction in critical situations in physics instruction. In these aspects a hierarchical progression from rather declarative aspects of PCK *(knowing that)* to rather procedural aspects of PCK *(knowing how)* can be seen (fig. 2).

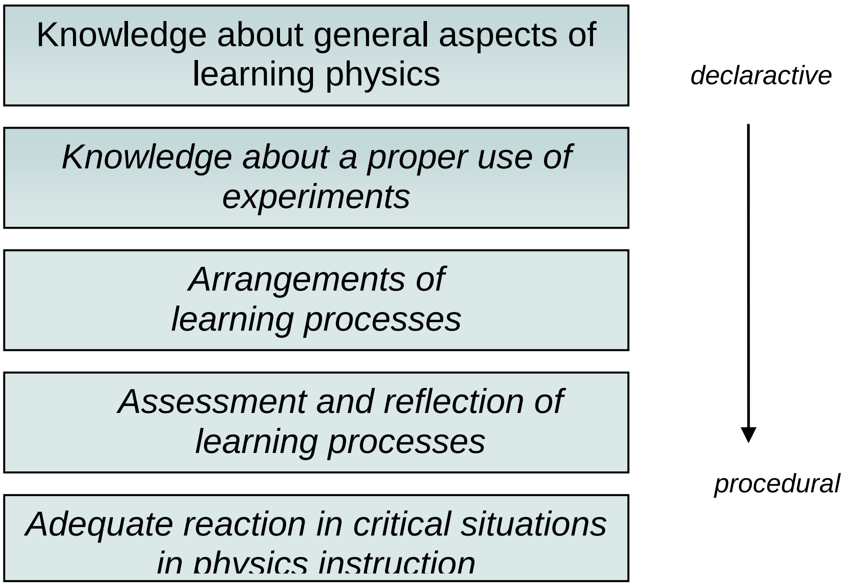

Figure 2 “Operationalization of PCK in physics”

METHODS

After concretizing the general structure of competence and the operationalizations of the diverse components of teachers’ professional competence, items for a questionnaire instrument were constructed to evaluate CK, PCK, PK, beliefs, attitudes and personality factors. To make sure that the instrument also assesses the (student) teacher’s ability to integrate, to associate and to apply the different components of competence, a pool of teaching-vignettes was developed. Teaching-vignettes are specific critical situations in the context of physics-lessons presented in the instrument, where the surveyed physics student teachers have to analyze the scene, to detect student misconceptions and to make a suggestion of how to continue in a reasonable way.

This instrument was piloted in a group of N = 45 physics student teachers attending one university. Afterwards the items were analyzed via descriptive statistics and factor analysis. Based on these analyses, the instrument was revised to get an empirically meaningful basis for further procedure. After that, the operationalization and parts of the questionnaire like the teaching-vignettes were validated by interviewing experts like experienced teachers, teacher trainers and academic physics educators. In doing so, the experts had to assess the critical situations with regard to relevance in respect of content and representativeness in a first step, and then they had to specify and categorize the tasks and problems. Finally, they had to explain how they would react in such situations in order to get adequate options for action within the sample solution. Moreover, the interviews were used to get further information to specify our model of professional competence of pre-service physics teachers. The once more adapted instrument was piloted in a group of N = 55 physics student teachers, now attending four different universities.

The main study was executed with about 430 students in lower and upper secondary level teacher education programs in several German federal states. For further validation, in a following study trainee teachers are investigated in order to explore to what extend components of their professional knowledge are related to distinct attributes of the quality of instruction regarding their classroom performance. While using the piloted questionnaire to assess their professional knowledge, a specific lesson (introduction of the force-concept in physics) are videotaped and analyzed regarding six main attributes of teaching quality in science instruction: coherent structuring, cognitive activation, motivational encouragement, scaffolding, classroom management and adequate use of experiments.

RESULTS

Psychometric Properties

After those steps of piloting the instrument, that was developed to survey physics student teachers' professional competence (see above), a well-working instrument is available now. The test's component related to teachers' PCK consisting of 39 items has a reliability of Cronbachs' $\alpha = 0.74$. Furthermore the shapes of the distributions concerning the test-persons' total score as well as the items' difficulties (fig. 3) imply that the instrument is neither too difficult nor too easy and that there is enough variance in the data.

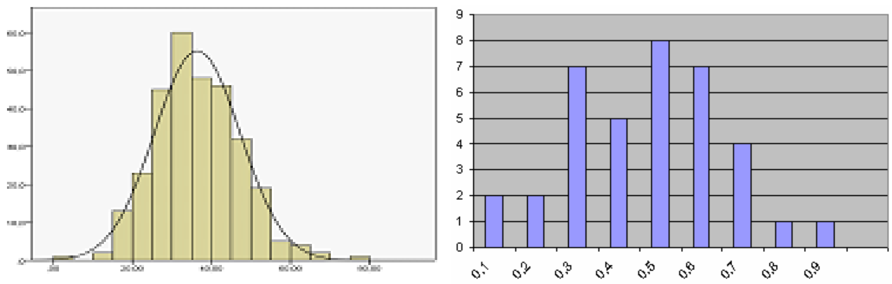

Figure 3 "Histograms referring to the relative total score in PCK (left) and the items' difficulties (right)"

In order to ensure the objectivity of the instrument, coding manuals with solutions based on literature as well as based on statements of experts (see above) were created. We found a good interrater-reliability randomly measured by intra-class-correlation (ICC = .91; $F(25,25) = 20.94$; $p < .001$).

We also carried out a criterion-related validation by comparing groups with different expertise levels (students, trainee teachers, teacher trainers) where we found increasing test scores for groups with greater expertise (ANOVA $F(2, 72) = 7.35$, $p = .001$). Finally, we tried to guarantee the construct validity by a combined data-collection with an independently developed instrument (Olszewski, 2010). We found a correlation between the two corresponding PCK-scores ($r = 0.64$) that was higher than the correlation of our PCK-part with our CK ($r = 0.45$) respectively our PK-part ($r = 0.49$) (fig.4). These correlations might indicate that PCK has a kind of middle-position between CK and PK and that CK and PK are prerequisites regarding PCK.

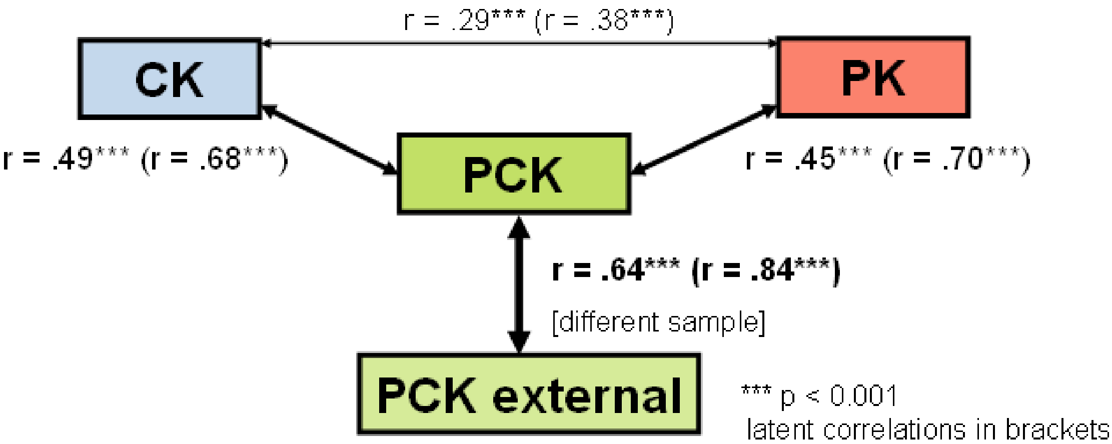

Figure 4 “Correlations within professional knowledge”

Comparison of different teacher education programs

In a first step, our study compares lower and upper secondary level teacher education programs. In a group of students within their last chapter of the academic study, we found significantly higher PCK-scores in upper secondary level programs compared with students in lower secondary level teacher education programs (p*< 0.001) (tab. 1).

education program / *professional knowledge*	*lower secondary level (N = 69)*		*upper secondary level (N = 69)*		*difference LL, UL*	
	M	***SD***	***M***	***SD***	***diff.*** M_{LL}, M_{UL}	$d_{LL,UL}$
CK	94.4	16.7	109.1	23.6	14.7 ***	.7
PCK	94.3	17.3	105.4	21.4	11.1 **	.6

Table 1 “CK- & PCK-Scores at the end of the academic part of teacher education”

Analyzing the reasons for this, we used a regression analysis to get findings concerning the development of physics student teachers' PCK. In this context, we found that the duration of corresponding parts of the education, respectively the amount of contact hours per week per semester, was identified as a significant predictor of students' PCK ($\beta = 0.15$, $p = 0.002$). This indicates that the lower secondary teacher education program is too short to bring out well trained teachers. Furthermore, the score of CK ($\beta = 0.38$, $p < 0.001$) and the final school exam grade ($\beta = 0.17$, $p = 0.001$) were further relevant predictors. In contrast, the total score in PCK doesn’t correlate with the number of corresponding college courses taken, which was used to measure knowledge in the past (cf. Abell, 2007). Apart from this, the number of semesters, the number of practical courses and student teachers’ gender were also no significant predictors regarding the score of PCK.

PCK and classroom performance

Concerning the relation between professional knowledge and classroom performance, very first results are available. In a pilot study, lessons of four trainee teachers and five student teachers were videotaped and the questionnaire instrument was used, too. The lessons were analyzed regarding six main attributes of teaching quality in science instruction coherent structuring, cognitive activation, motivational encouragement, scaffolding, classroom management and adequate use of experiments. Therefore high-inferent ratings of the teachers' actions in the classroom were carried out for every single attribute using four-point-likert-scales.

Rank correlations *(Kendall's Tau)* between the total PCK-Scores (N=9) and the ratings (on a scale from 1 to 4) show no significant correlation (as expected due to the small sample) (tab. 2). But there seems to be a tendency for a correlation between a teachers' performance concerning the cognitive activation of students in the classroom and the acquired pedagogical content knowledge (cf. Olszewski, 2010).

	Motivational encourage-ment.	***Cognitive activation***	***Coherent structuring***	***Scaffolding***	***Classroom management***	***Use of experiments***
PCK	*.141*	*.310*	*.171*	*-.141*	*.085*	*.059*

Table 2 „Rank Correlations between attributes of teaching quality and total PCK-Score"

But these results lacks validity as the comparability of the videotaped lessons is not sufficient because the student teachers mostly did not perform an introduction in the force concept.

CONCLUSION AND IMPLICATIONS

In view of the current discussion with regard to a reorganization of the first phase of teacher education, our study provides a statistically well working instrument to measure different aspects of physics student teachers' professional competence including PCK based on a theoretical model of competence. Surveying students of different teacher education programs, we are able to identify shortcomings and therewith potential improvements in the process of upcoming pre-service teacher education reforms. At the moment, our instrument is validated with regard to high-quality instruction by analyzing physics lessons in a standardized setting (introduction of force concept). After the data collection of the corresponding video study is completed, further in-depth analyses will allow detailed findings concerning the interplay of the different components of PCK (measured by the paper-and-pencil-test) and physics teachers' quality of acting in real classroom situations.

TEACHERS' VIEWS ABOUT PRACTICAL WORK IN UPPER PRIMARY AND LOWER SECONDARY SCHOOL: ANALYSIS FROM A MODEL BASED INQUIRY PERSPECTIVE

Cristina Rodríguez-Simarro[1] *and Digna Couso*[1,2]
[1] CRECIM
[2] Mathematics and Science Education Department, Universitat Autònoma de Barcelona

Abstract: Despite the important role that science education seems to give to practical work, research has reported during years a lack of effectiveness of the approaches implemented in the science classroom. The research presented in this paper proposes a model-based inquiry framework[1] for practical work and uses this framework to analyze teachers' views about it. These views are obtained by analyzing personal interviews on both teachers' perceptions and reports of practice, including the analysis of teachers' actual designs of practical work activities. From this analysis, some profiles are identified. Our first results indicate that, in general, practical work seems to be important for teachers despite the existing didactical approaches to it are quite traditional. Nevertheless, some of them are interesting to be taken into account as a possible point of departure for a model-based inquiry approach to science teaching and learning, bearing in mind the facilitators and limitations encountered by teachers identified in the analysis carried out.

Keywords: practical work, inquiry based science education, model based inquiry

INTRODUCTION

The interest of this research emerges from the results obtained within the research done during the first phase of TRACES[2] project, where a sample of n= 207 primary and secondary school teachers' answered a questionnaire related to their views regarding effective science teaching. First analysis highlighted the important role given to practical work, but also suggested the existence of a broad range of perspectives regarding its approach with some differences between primary and secondary school teachers' views.

In the light of these first results and considering the authors' interest on model based inquiry science education, the designed research was addressed to answer the question: *Which are teachers' views in upper primary and lower secondary regarding practical work and how these views can foster or hinder a model based inquiry science education?* This research then pretends to enlighten the research findings about practical work in the science classroom from the perspective of one of the didactical approaches that are being supported by the science education research community. To do so, the proposed research has three objectives: to propose a framework for practical work from a model-based inquiry perspective; to characterize upper primary and lower secondary school teachers' views regarding this framework; and to identify possible differences and similarities between primary and secondary school teachers' views from this specific teaching and learning perspective.

THEORETICAL FRAMEWORK

Practical work in science education

Practical work is usually considered as a quality indicator for science education. According to some authors it can facilitate the learning of some important scientific procedures such as observation, hypothesis proposals or the analysis and interpretation of results and can help students to elaborate an appropriate image of scientific activity (Hodson, 1994). In spite of its potential, however, analysis of the practical work being traditionally carried out in school has pointed out a general tendency of practical work to be ill-conceived, confused, unproductive and lacking in educative value (Hodson, 1994). Due to this mismatch between what would be expected and what is actually carried out in schools, research has devoted a lot of effort in trying to clarify which should be the main objectives of practical work. Last studies conclude that these objectives are to develop in students: manipulative and observational skills, the ability to interpret experimental data and to plan experiments, the interest in the subject and a feeling of reality regarding the phenomena being studied in theory (Johnstone & Al-Shuaili, 2001).

For some authors, it is the last point mentioned which constitutes the main purpose of practical work that is to help students to link the real world of objects, materials and events with the more abstract world of ideas and theories (Tiberghien, 2000). Unfortunately, some research results show that there are few evidences about the inclusion of this purpose in the practical work designed by teachers.

Model-based inquiry as a didactical approach

Research seems to confirm, despite the lack of existence of definitive results regarding it, that teaching and learning approaches centered on learning by inquiry (Inquiry-Based Science Education or IBSE) produce positive results related to students' motivation and science learning (Minner et al., 2010). In this sense, there is a general consensus in the literature that IBSE is central for science education (Barrow, 2006), despite claims about IBSE not being the only strategy to be used in the classroom and possibly not an approach to learn all sorts of scientific contents.

Beyond these considerations, research reports a lack of agreement about what IBSE is referred to. In our study we will be based on the literature review made by Barrow (Barrow, 2006) to define the dimensions that characterize IBSE: a) the cognitive abilities that students must develop; b) an understanding of methods used by scientists to search for answers for their research questions; and c) a variety of teaching strategies that help students to develop their abilities of inquiry (a), learn about scientific inquiry (b), and understand science concepts. Regarding them, there is more research consensus regarding what has to be taught to students than how teachers should teach from an IBSE approach (Anderson, 2007). In last years, research has been focused on the dynamics of IBSE and how to bring it to the classroom because despite research has confirmed the feasibility of bringing this approach to science classrooms there are a lot of studies confirming that this approach has not reached yet the expected quality levels. Barriers, external and internal, have been identified when trying to bring IBSE to the actual classroom practices (Barrow, 2006).

Based on the National Science Education Standards of the NRC five essential characteristics are highlighted: 1) scientifically oriented questions that will engage the students; 2) evidence collected by students that allows them to develop and evaluate their explanations to the questions; 3) explanations developed, by students from their evidence to address the questions; 4) evaluation of their explanations, which can include alternative explanations that reflect scientific understanding; and 5) communication and justification of their proposed explanations. These five characteristics entail some hands-on but also minds-on activities for students that form what will be named as *IBSE cycle*.

Among the most important critics to the consideration of IBSE as a privileged teaching and learning strategy is that of relating IBSE good results to the measurement of students' enthusiasm instead of to the actual learning of scientific contents and relation of IBSE with mere procedural and manipulative tasks and learning. In her article Viennot (2010) urges for the need to develop a more conceptual component of IBSE approaches, seeking to guarantee students' understanding of scientific concepts. For the author, IBSE approaches should be addressed to systematize and organize scientific concepts (more theoretical or more linked to theory) even though these approaches are usually considered as too traditional.

Last aspect we think is essential to be clarified is referred to some epistemological problems that we can find in the IBSE approaches commented until now. We are talking about the fact that, depending on how it is interpreted, inquiry activities can be centered on students' local explanations (the ideas they induce from their experiments and research designs) without any connection with any scientific theory that is seek to teach and to be learnt. Some authors identifying incomplete inquiry practices make reference to practices that are influenced by what is called the *scientific method* (Windschitl et al., 2008) highly widespread among teachers and that gives an unproblematic image of science, oversimplified forms of reasoning and often theory dissociated. According to the authors, a very systematic science that tends to present a unique way of gathering evidences, directly from practical work and without a connection between concepts, laws, principles or scientific models. This approach leads to the superficial explanations mentioned before, that give only answer to a concrete situation but not going beyond. Facing this situation, the research that proposes another way of understanding inquiry having in mind constant connections between phenomena and theory claims for an inquiry that focuses on the construction of models: representations constructed as conventions within a community to support disciplinary activity (Windschitl et al., 2008) or reasoning structures that allow someone to generate predictions and explanations (Schwarz & Gwekwerere, 2007). This particular model-based approach to IBSE is in agreement with the aforementioned views of practical work connected with theory.

Practical work from the perspective of model-based inquiry

Trying to foster the implementation of inquiry approaches in the science classroom and according to some research results that confirm that practical work can help to the promotion of inquiry (Barrow, 2006), this research proposes a framework for practical work from a model-based inquiry perspective. Based on the traditional IBSE cycle mentioned before, a cycle for practical work could be defined taking into account the potentialities of practical work above mentioned (see Figure 1). Additionally, based on the proposals of a model-based inquiry perspective, we could locate this practical work cycle in two dimension space that include the objects' or observables' world dimension and the ideas' or theoretical world dimension. The ideas world must go beyond students' ideas and make reference to students' constructs that should be in agreement with the scientific theories we want students to learn. The observable world refers to the phenomena observed and the experiments carried out in the science classroom. In a model-based inquiry framework as the one proposed, practical work should be situated in these two worlds, as the context in which to promote scientific reflection and learning, connecting both worlds by a modeling process. Figure 2 tries to represent this proposal.

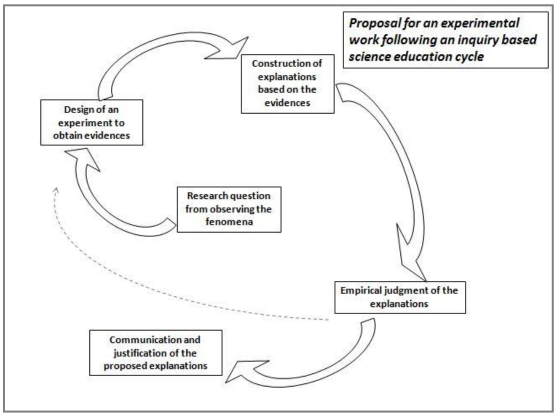

Figure 1. Proposal for a practical work following an IBSE cycle

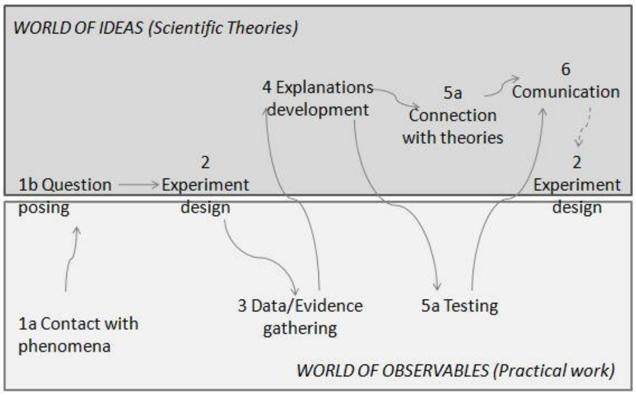

Figure 2. Practical work following an IBSE cycle: connections between the world of ideas and the world of observables

METHODOLOGY

This research is situated in a qualitative and interpretative research paradigm. Giving the interest of this research on the possible differences and similarities between primary and secondary school teachers, the study addressed the views of four upper primary (M1, M2, M3, M4) and four lower secondary (P1, P2, P3, P4) teachers from both public and semi-private schools.

Data collection

Trying to connect teachers' views regarding practical work to their own practice, the selected instrument for the data collection was a semi structured interview in which to discuss practical work teaching and learning activities both specially designed for the interview and also coming from the interviewed teachers. The interview was structured in three main blocks that are summarized in Table 1. All interviews were audio-recorded, being this the main source of data. Video data and other sources such as researcher notes and the documents related to the teachers' practical work proposals that guided the interview were used as secondary data.

Block	Description
Block 1 Practical work dimensions	Teachers' views about: main objectives, expected learning, role of practical work in classroom activities, format (including main students tasks), link with theory, teachers' role and evaluation.
Bloc 2 Personal experiences	Narration of own experiences as students regarding science and practical work; view regarding differences between primary and secondary.
Bloc 3 Opinion regarding non inquiry/inquiry activities	Teacher's selection according similarities with their own proposals between two practical work activities given by the researcher (both activities working the same concept, but one more closer to an IBSE approach)

Table1. Interview structure

Data analysis

Data analysis was carried out in three phases: a first analysis of teachers' views regarding practical work; a second phase in which, starting from the first phase results, some teachers' profiles were defined by considering the existing gap between their views and a model-based inquiry approach of practical work according to the proposed framework; finally, a deeper analysis regarding the factors that could be influencing the proposed profiles.

First analysis was done with Atlas.Ti, labeling those snippets considered more relevant taking into account some aspects coming from the theoretical framework (and already considered when designing the interview) and other ones that were emerging from data while making this first analysis. The considered dimensions were: *Practical work aims, Expected students' learning, Practical work structure, Students' tasks, Teacher's role, Link between theory and practical work, Limitations and facilitators to propose practical work* (in general and with an inquiry approach).

In the second phase and for each of the mentioned dimensions, categories that reflect a closer view to a model-based inquiry approach were identified, together with those reflecting a view not in agreement to this framework. Those requirements considered essential to *facilitate* inquiry, that is, fitting to the inquiry framework defined in this research, were defined for practical work *aims*, expected students' *learning*, students' *tasks* and *link with theory*. Those aspects that were considered to *hinder* inquiry as is understood in this research were also identified when characterizing a more traditional practical work approach or with a non modeling inquiry approach. Finally, some categories were identified that would *difficult inquiry to a higher degree*, being so far from an inquiry approach that the gap for a methodological change would be hard to be achieved. Linking the first and second analysis results, a deeper understanding of which factors could influence teachers' views was sought in order to be able to assess which mechanism could help teachers' views to evolve towards a model-based inquiry approach.

RESULTS

First results of the analysis were synthesized in sistemic networks in which teachers' answers were classified. By way of example, Figure 3 presents the one of the networks for the dimension "aims of practical work". According to this analysis, we could confirm that main aims considered by teachers were *motivation* in the case of primary school teachers, and *contextualization* of theory, for secondary school teachers.

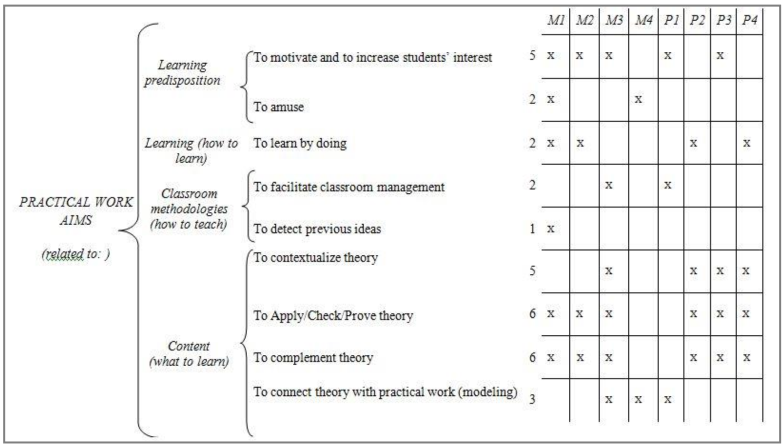

Figure 3. Analysis of teachers' answers regarding practical work aims

For the rest of the analyzed dimensions, some results could be highlighted. Regarding the expected learning, teachers tend to mention the learning of *science contents*, but other learning targets such as *cognitive abilities* or *nature of science* are less considered. When talking about the *tasks* students should carry out when being engaged in practical work, main references are made to *execution* tasks such as use of devices but there are few teachers bearing in mind important tasks from an IBSE point of view such as *planning* or *analysis*. Related to an important aspect of the framework defined in this research, the *link between practical work and theory*, most of the interviewed teachers tend to place theory before practical work, in a one way direction link in which once the theory is given, practical work can be started.

For the second phase of the analysis, some criteria were defined for the categories taking into account if they would *hinder* or *facilitate* an inquiry approach such as the one elaborated in this research. This criteria was used to classify teachers into *inquiry profiles (regarding their conception of IBSE)* as we will see further on. Following with the example of the dimension "aims of practical work", Table 2 shows this classification proposal.

	Practical work aims	
1	If only aspects related to learning predisposition (to motivate/to amuse) are mentioned	*Highly hinders inquiry*
2	If only aspects related to how to learn (empiricist view: learning by doing) are mentioned	*Highly hinders inquiry*
3	If only aspects related to classroom methodologies are mentioned	*Highly hinders inquiry*
4	If, when talking about content, only contextualization is mentioned	*Hinders inquiry*
5	If, when talking about content, the link between theory-practical work is considered but only in one way sense (theory→ practice or practice → theory)	*Hinders inquiry*
6	If, when talking about content, the link between theory-practical work is considered in both sense, with the objective of constructing models	*Facilitates inquiry*

Table 2. Criteria for teachers' inquiry profiles according to their views regarding practical work aims

Once these criteria were defined, also for the rest of dimensions and categories, teachers were classified into *inquiry profiles* considering if their views could hinder or facilitate a model-based inquiry approach for practical work. Taking again "aims of practical work" as an example, teachers were classified as shown in Table 4.

	M1	M2	P3	P4	P2	M3	M4	P1
Practical work aims	*Hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Facilitates inquiry*	*Facilitates inquiry*	*Facilitates inquiry*

Table 4 Analysis of teachers' views regarding pratical work aims from the perspective of model based inquiry science education

Applying these criteria and classifying teachers into profiles for the considered dimensions, a global *inquiry profile* was defined for the interviewed teachers' views (see Table 5).

	M1	M2	P2	P4	M3	P3	M4	P1
Global	*Highly hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Hinders inquiry*	*Facilitates inquiry*	*Facilitates inquiry*

Table 5.Teachers' views profiles taking into account to what extent they facilitate a model based inquiry approach for practical work

Being these results quite revealing, with most of teachers (both primary and secondary levels) offering views regarding practical work partially far from an inquiry approach but with some potentialities to get closer to this approach, it would be interesting to go further on this analysis trying to identify which could be the mechanisms to make evolve these views by considering the facilitators and limitations mentioned by teachers themselves. To do so, the global profiles defined in the second analysis are correlated with the limitations stated by teachers, classifying these limitations as internal or external considering if they were directly related to teachers, their beliefs and their level of self reflection or if they were more influenced by external factors, such as structural limitations. Figure 4 presents this correlation. As we can see in the graphic, teachers with naive views of inquiry, far from the proposed framework do state both external and internal limitations, although for primary school teachers only external limitations are mentioned. On the other hand, teachers with more sophisticated inquiry views do only state external limitations, which would suggest that for these teachers internal ones have been overcome. Finally, there is only one case in our sample with views further from an inquiry approach, which makes hard for this study to draw any conclusion despite it seems that both external and internal limitations are present.

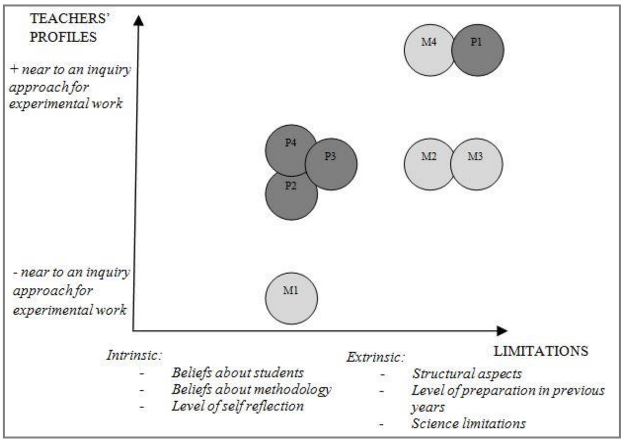

Figure 4. Proposed profile for the classification of teachers' views about inquiry practical work. Correlation with stated limitations.

Trying to overcome these limitations, also an analysis of the possible facilitators should be done. In one hand, for teachers with medium inquiry views, that is those presenting some potentialities to use a model-based inquiry approach in their practical work, we could say that this view was favoured in situations in which they have collaborated with other colleagues or when they have been involved in some specific projects (such as an ICT project). Also when they master the subject they are teaching they feel more confident to carry out different approaches such as an inquiry one. On the other hand, both teachers presenting a profile that virtually fits with the inquiry framework proposed in this research had in common that they have had a regular contact with research and innovative groups, being an important mechanism to be taken into account.

CONCLUSIONS

This research has made possible to elaborate a framework to characterize a way of proposing practical work that fits within an inquiry based science education (IBSE) approach, specifically that of model-based inquiry. The analysis of the interviewed teachers' views regarding practical work from this framework suggests that, despite the existence of some differences between primary and secondary school teachers' views, there is not too much to highlight regarding these differences. Practical work has still an important role for teachers in science education, but the proposed approaches are quite traditional which would suggest that a renovation of this practical work inspired in the proposed inquiry framework could be beneficial at two levels: first, to take advantage of practical work potentialities, widely highlighted by research in science education; and second, as a first step to bring inquiry approaches closer to the science classroom by introducing this perspective to guide something that it is already done. In this sense, the fact that the majority of the interviewed teachers present views with some potentialities for an inquiry practical work, would suggest the feasibility of this approach.

Regarding the methodology proposed for this research, the fact that the interview has been developed around teachers' own practical work designs has make possible to analyze their views from an approach closer to their real teaching practice. On the other hand, to give to teachers the opportunity to see a traditional practical work activity transformed into an inquiry approach (block 3 of the interview) has allowed teachers to contrast their own teaching practice with both alternatives, helping to emerge the limitations and facilitators that could condition their day by day selection between one and the other approach. Finally, we think that the proposed dimensions and categories for the analysis of teachers' views can be used as a basis for future large scale studies.

NOTES

[1] The inquiry framework developed in this research has been carried out in the context of discussing the nature of scientific competence in the I+D project COMPEC "Análisis de dificultades, propuestas de formación y elaboración de materials didácticos como "buenas prácticas" en el ámbito", ref. EDU2009:08885, Ministerio de Ciencia e InnovaciónTransformative

DESCRIPTION OF PRACTICE TEACHING FROM THE SYSTEMATIC OBSERVATION OF THE WORKING CLASS IN HIGH SCHOOL

Diana Rodríguez[1] *and Ángel López-Mota*[1]
[1]Universidad Pedagógica Nacional, México

Abstract: Addresses the practice of teachers of science, research phenomenon through a detailed analysis of previous classroom sessions video-recorded, three in average teacher, "from an" Analytical Model of Teaching Practice, from Systematic Observation ', in which each session is divided into 5 minute clips to be analyzed, having a total of up to 10 clips per class session, to record the frequency of video-recorded events which identifies the presence or absence of actions of each of the five categories of analysis of teaching practice, previously established role of student, teacher role, learning object, the object of evaluation and assessment concerning ", which allows statistical manipulation data.

The characterization of work in the classroom of high school science teachers, we can provide information regarding the key elements that constitute the practice of teachers. Preliminary results show academic activities typical of a traditional practice, characterized by the absence of experimental activities, making it necessary to rethink the training and retraining of teachers in the exercise of basic education in Mexico.

Keywords: teaching practice, systematic observation, science teacher education, working class

INTRODUCTION

-The Problem

Previous research work on teacher's initial and in-service training (Rodríguez & López-Mota, 2006) reports that despite teachers taking many in-service courses, there are few signs of significant changes in teaching as well as in learning science. This leads us to think that there is a problem with the nature of work developed within the classrooms that is not easily changed by either initial training or in-service courses. So it seems interesting to know why it is so hard to change it, by understanding what it is the kind of teaching practice displayed within the classrooms.

Recent studies about the teaching practice, based on video recorded sessions, have given solid empirical basis to develop quality teaching (Roth et al., 2001; Duit et al., 2005). Nevertheless, several researchers (Lederman, Wade & Bell, 1998; Tsai, 2002) express their concern for having at not hand much more needed results on what happens within the classrooms at schools.

With this research we wanted to characterize what happens within classrooms -as a direct phenomenon of study- by analyzing detailed previously recorded sessions -three on average for every teacher- taking on board an analytical model of teaching practice, based on systematic observation.

-Framework

The teaching practice has been studied under several perspectives: practical implications from theoretical perspectives (Pozo & Gomez, 1998; ethnographical approaches (Candela, 1999) and description of the phenomenon (Duit et al., 2005; López-Mota, Rodríguez, Flores, Martínez & Antonio, 2007; Rodríguez, 2007; Flores, 2009).

The first perspective towards teaching practice is derived from theoretical stands of learning traditional, discovery, significant and constructivistic- but does not offer empirical evidence to justify such categories. The second one comes from an ethnographical point of view and describes cases of what happens within classrooms, but having problems in developing large scale studies because of its methodology. The third one -in which is based the present study- offers an advantage: the systematic description of teaching practice (Flores, 2009) who has defined analytical categories and empirical indicators of pedagogical actions of teachers within the classrooms.

RATIONALE

This type of investigation might bring new light to establish educational policies, based on extended empirical data and bring about changes in the nature of the teaching practice in the classrooms. We think it is eventually possible to develop a theory of teaching practice if we base our descriptions of what happens in the classroom, in an analytical model that is as well based on systematic observations. This means, with the aid of cognitive theories of learning and analytical categories coming from observation: a strategic blend of *apriori* and *aposteriori* procedures.

METHODS

To characterize the educational practice of natural science teachers, through its detailed analysis of video-recorded class previously, we initially set out to build a *'Analytical Model of the Teaching Practice from the Systematic Observation*' (*MAPADOS*) -by its Spanish acronym- (López-Mota, López, Rodríguez & Flores, 2010), which is constituted two categorical systems whose behavioral taxonomies are the product of previous work (López-Mota et al., 2007; Flores & López-Mota, 2009) and from the conceptual level. The first categorical system, which is used in this work, consists of five analytical categories: *student role, teacher's roll, object of learning, evaluation object and references for evaluation.* This taxonomy has the virtue of indicators, from 4 to 10 for each category, originate from an empirical analysis of classroom observation (Flores, 2009), giving a total of 29 shares for the 5 categories with which analyze teaching practice, which allows a wide range of actions taken by the teacher in the classroom work. By splitting the sessions in clips of 5 minutes you get a large number of events to analyze, the model proposes to sweep the observation of more than 50% of each class session, recording only what happens on the odd or even for clips each class session, but always recording what happens in the first and last clip of the class.The model implies that each videotape, for a class session, which in theory is 50 minutes, split into 5 minute clips to be analyzed, having a total of up to 10 clips per session of class to record the frequency of video-recorded events in which it identifies the presence or absence of actions of each of the five categories of analysis of teaching practice previously established statistical manipulation of data.

-Procedure

To make it possible to obtain the reliability of the observations, it was necessary that pairs of observations were made of each category in the same teacher. To then get the percentage of agreement, the margin should be at least 80%.We apply the methodology 1 of MAPADOS at a sample of 17 science teachers, biology, physics and chemistry in secondary schools from morning and afternoon in Mexico City.

RESULTS

The 17 teachers were observed in a total of 45 class sessions for an average of 2.64 sessions per teacher, as class time in schools is 50 minutes, total time, in theory, intended for these kinds of science was 37 hours. But when doing field work, we find that the reality was that the 45 class sessions lasted 28 hours and 9 minutes, which is losing roughly 25% of the time devoted to work with students.

Which does not lead to identifying a first point on which we must work in order to ensure the quality of education, especially when the faculty have spoken out against the curricular reforms by lower -apparent- content in the plans study.

By dividing the class sessions in clips of 5 minutes was possible to obtain a total of 331 events to be analyzed using 29 indicators, but because the model does not propose to analyze 100% of the session, but a scan class representative in this case 210 clips were found which means were analyzed 17 hours and 51 minutes, which gives a percentage of scanning for the analysis of the kinds of 63.41%, which is a fairly representative value of teaching practice. Concerning the characterization of teaching practice, Table No. 1 shows the results of the 17 teachers under the teachers' actions more frequently in the classroom. Table No. 2 shows the results of the 17 teachers under the teachers' actions less frequently in the classroom.

Regarding the most common registered shares in the class of teachers, it is noteworthy that occupies the first place-for the total sample, make reference to the behavior of the students: "Students keep composure before the intervention or activity performed by the teacher". And the other four refer to an expository teaching practice in which students act and interact primarily at the express request of the teacher. In contrast, the least favorable action in the classroom is referred to the students participate on their own initiative. The other four actions that are least in teaching are in the same vein, it does not refer to the possibility of interpretation of science or phenomena by students and the lack of real interaction between them and the teacher beyond listening.

Table No. 1: Stocks with greater frequency

Category	Action	Frequency	Subjects
Student role	I-6: Students keep composure before the intervention or activity conducted by the teacher	162	17
Object of Learning	III-1: The teacher displays or presents the content or phenomena using definitions and / or contextualized and / or instantiations, without room for interpretation by the students.	111	17
Teacher's rol	II-1: The teacher verbally, with or without teaching aids, described or set forth concepts and ideas of school knowledge	98	17
Student role	I-2: The student writes a specific request or at the direction of the teacher.	97	16
Student role	I-6: The student teachers expressed or spontaneously request a verbal response, written or graphic, or a direct challenge to the group in general.	93	16

Table No. 2: Stocks with less frequency

Category	Action	Frequency	Subjects
Student role	I-7: The student takes the initiative itself part of the exhibition of the teacher and express in their own words, to broaden the understanding of the learning object	1	1
Object of Learning	III-4: Teaching materials and resources used to define and / or contextualize and / or exemplify, with room for interpretation by the students.	7	2
References for evaluation	V-3: The teacher points out the differences in performances that have a student for himself.	8	4
Object of Learning	III-2: The teacher displays or presents the content or phenomena giving room for interpretation by the students.	10	3
Teacher's rol	II-6: Happens to teams during the implementation of a pilot, or not being able to interact with students	15	6

CONCLUSIONS AND IMPLICATIONS

We can say in conclusion that it is possible to account for the practice of teaching as a phenomenon of study, from the detailed description of it by categories of analysis that are reflected in the actions taken or not teachers at its class. As the core elements to characterize the work in the classroom of high school science teachers, we find that your practice focuses on the exposure of content through definitions and/or contextualize that leave no room for interpretation by the students, lack of laboratory practice into context the phenomenon to study and teaching practices that enable centralized interaction among students about scientific knowledge and assessment activities focused on compliance or otherwise of the activities tasks and / or product class and not in the analysis of individual performances of each student.

IN-SERVICE BIOLOGY TEACHERS´ PCK DEVELOPMENT: ANTITHETIC ROLES OF SELF EFFICACY

Martin Scheuch[1], Erika Keller[1] and Franz Radits[1]
[1]Austrian Educational Competence Centre of Biology, University of Vienna

Abstract: The focus of this study was the development of pedagogical content knowledge (PCK) of two teachers during a professional development course in biology. Pre and post interviews as well as recordings during the course made it possible to track whether PCK was developed or not. Self efficacy was the central PCK component, enabling development in Bert's case and hindering it in Anna's case. This study demonstrates the importance of this PCK component and the importance of the connections between the components for integrated PCK development.

Keywords: biology, professional development, pedagogical content knowledge, PCK development, self efficacy

INTRODUCTION

The context of this paper is the development of a professional development (PD) course (Scheuch, Keller, Radits, & Pass, 2010) in biology to improve teaching of field ecology. The overall aim of the course is the development of in-service biology teachers' pedagogical content knowledge (PCK); the teachers choose the emphasis for their learning individually. In this study, which addressed the development of PCK of teachers through participation in this PD course, the PCK component self efficacy emerged as a central component enabling and disabling development.

THEORETICAL BACKGROUND

Professional Development

Reviews by Lipowsky (2010) from a pedagogical view and by Hewson (2007) specifically in science education research, have revealed the following factors for effective PD courses: 1) The duration of the course is important – the longer the course lasts, the more development can take place and the more of the content of the course is transferred to the participants' classes. 2) Exchange between the teachers and sharing work on their teaching are needed to further develop their understanding about what they are doing in class. 3) Teaching practice should be included, so the PD course should challenge the classroom practice within its programme as well. 4) The teachers' experience based on former practice and the practice conducted within the courses should be reflected. 5) PCK as professional knowledge domain should be addressed explicitly in the course by the teacher educators as well as the teachers. In studies which focus on the development of PCK in PD courses, the factors of effective PD have also been found (e.g. J. H. Van Driel, Verloop, & Vos, 1998: changing craft knowledge of teachers needs reflected teaching practice and the focus on the learning of the students).

Pedagogical Content Knowledge

Pedagogical content knowledge (PCK) is a domain of teacher knowledge (beside pedagogical knowledge and content knowledge), which is important for the teaching of a specific subject and even a specific topic (Shulman, 1986; 1987). PCK research is a very wide area, with lots of different conceptions and attributions of PCK. One tension has to be mentioned: Although it is described as the "*special form of professional knowledge*" (Shulman, 1987, p.8), it is individually developed and far from being a collective body of knowledge. Cochran et al. reacted with a constructivist conception in replacing PCK by PCKg (that means pedagogical content knowing and also includes more tacit forms of knowledge) or more recent Wieringa (2011) in her re-reading of Schön´s “The Reflective Practitioner” (1983) where she sees PCK as some kind of practical knowledge – opposing formal knowledge. These different characteristics are a result of the individual development of PCK, as it is developed by the teachers during practice of teaching and the reflection upon the practice (Park & Oliver, 2008; J.H. Van Driel, Jong, & Verloop, 2002); therefore it results in an individual or idiosyncratic knowledge (Park & Oliver, 2008; J. H. Van Driel & Berry, 2010). Abell (2008) asks for an overarching model of PCK development, because actually the developmental routes of the teachers are very isolated (Abell, Rogers, Hanuscin, Lee, & Gagnon, 2008). Park & Oliver (2008) developed one model based on Magnusson, Krajcik et al. (1999), where the growth of the teachers’ PCK is central. Reflection in Action as well as Reflection on Action turned up to be crucial (Park & Oliver, 2008). In a most recent review about studies documenting PCK development, Schneider & Plasman (2011) have found general developmental pathways during teaching biographies for the several components within the PCK conception of Magnusson et al. (1999). So there have been and still are attempts in getting the development conceptualised; in this paper we take the model of Park & Oliver (2008) because this matches our intentions best. The six components are: Orientations to Teaching Science (OTS); Knowledge of Students’ Understanding in Science (KSUS); Knowledge of Science Curriculum (KSC); Knowledge of Instructional Strategies and Representations for Teaching Science (KISR); Knowledge of Assessment of Science Learning (KA); Teacher Efficacy (TE). Teacher efficacy was newly introduced into the model by Park & Oliver (2008) and labelled as “*an affective affiliate of PCK*” (p 270). They described that it “*was a highly subject specific version of teacher efficacy in that it was related to teacher beliefs about their ability to enact effective teaching methods for specific teaching goals*“(p 270).

RESEARCH QUESTION

Our research question addresses the development of teachers’ PCK in ecology: How does the teacher’s PCK develop by participating in our in-service PD course? In this paper we focus on the role of self efficacy in the development of PCK.

METHODS & PARTICIPANTS

The pre-post interview study follows a pragmatic research approach because the results should help to improve further courses. The first interviews were conducted before the course started and the post interviews were held one to two years after the course. The interviews were semi-structured, guided interviews with longer narratives about biology classes in the topic ecology and outdoor biology. Hashweh (2005) made clear that planning instruction as well as reflecting lessons elicits teachers´ PCK, therefore those narrative sections about their lessons were important. Previous studies (Keller & Scheuch, 2010a, 2010b; Scheuch & Heidinger, 2009) were conducted to develop the research rationale and the interview guideline. Additionally included were questions of the teacher beliefs interview (Luft & Roehrig, 2007), to make the teachers reason about teaching ecological topics. The teachers were asked to present a teaching sequence they were proud of; the interviewer used questions to highlight every aspect and to get an overall impression of this/these sequence/s.
In total, 23 teachers participated in the course from primary school to upper secondary school. The four volunteers participating in the study were experienced teachers and studied at University of Vienna for lower and upper Secondary Schools called Gymnasium.

Teacher (synonym)	Subjects	Teaching practice (yrs)	Age
Fiona	Biology, Sports	9 (recently came back after maternity leave)	47
Clara	Biology, Zoology	6 (worked as biologist before)	45
Bert	**Biology, French**	**12**	**38**
Anna	**Biology, Religious Education**	**26**	**54**

For this paper we focus on **Anna** and **Bert**, because in their cases self efficacy turned out to be the most important PCK component.

Data Analysis

The data - from interviews as well as from recordings collected during the course - were transcribed verbatim; the latter were working sessions in the afternoon, plenary discussions in the evening, a discussion about reflecting a lesson with the model of PCK itself, course feedback by all participants. The transcripts were coded with deductive PCK categories derived from Park & Oliver (2008). The methodological approach was the qualitative content analysis by Mayring (2010). Each teacher was partly coded by a second person as well – the coding and understanding of the interpretation were discussed until common sense was reached and the blurriness of the applied categories was clarified. Based on this analysis a case study for each teacher was elaborated, reconstructing the teachers' reasoning out of the reported results of the PCK interviews. Those reconstructions include descriptions of the teaching by the teachers including their orientations, aims as well as routines. These reconstructions can be looked at as being the subjective theories of the teachers. In the results of the PCK development only explicit PCK development was considered, which means that the teacher had to make his/her growth explicit and/or the process data helped to identify the progress. Data triangulation with transcripts of process data was conducted for validation of the reported PCK development by the researchers. All other developments, which could also happen easily during almost three years of teaching, were excluded.

RESULTS

In this section the two cases are presented. The results are structured as follows: First their overall subjective theory of teaching their topic; Second the component of self efficacy and connections to other PCK components; Third the PCK development we detected.

Bert

Subjective theory of Bert: The content, in this case ecology, is very important for him. He is fond of good lesson preparation, and further refinement of his lesson plans reflecting the experience is important as well; so he continuously improves his biology classes. He is aware of his students´ interests and tries to include them in his biology class, e.g. he encourages his students to bring interesting phenomena to his class. He works with complex assignments to elicit the understanding of his students – not only to get the grades, but to get feedback about the students' understanding as well. Another focus is the preparation of the students for future written exams in biology at upper secondary levels.

Results from the pre interview: The category of self efficacy occurred in two ways. First, when he looked back at his biography as a novice teacher. In earlier years he easily drew back when there were difficulties by his students in understanding a topic and developed resistance to the teacher and the topic. He avoided the resistance and did not engage in the students´ learning. Later he developed strategies to cope with this problem. The component SE is connected with the KSUS, resulting in a different teaching strategy (KISR) with a curricular argument (KSC). A quotation to illustrate the analysis:"*...for example osmosis. Earlier in my career I taught it and finished it, knowing that not everybody had understood. I didn't want to talk for another three lessons, because I had already told them everything. Now I am converted, I give them more examples; my students make experiments on that topic. That needs more time, but now I know that I can build on that knowledge later on. For example in the context of teaching excretion…."* (pre-§62). Asking for his expectations for the PD course he stated: *"…It is most delicate for a biology teacher to go outdoors; you can easily look like a fool. […] I think that it helps to develop more routine and know more methodological approaches, […], these aspects were neglected in my pre-service education."* (pre-§138). So he wanted to get more SE during the PD course for his future outdoor teaching through learning new strategies and methods (KISR).

Bert planned and conducted a teaching sequence with fieldwork in the first grade of lower secondary level (kids aged 10-11 years) during the PD course. The topics were “seeds and fruits”. The class consisted of high achievers who were expected to complete the lower secondary level in three instead of four years.
Results from the post interview: Bert was more confident in dealing with less favoured topics like plant families, his self efficacy had developed along with a teaching strategy. He gave the students more time to elaborate on a topic: *“With animals it would be easier, but with plants […]. For years I had had the material about common plant families in my drawer and this year I tried to use it. Asteracea, Lamiacea and so on…, and this topic was not received enthusiastically. I had to face resistance for a few lessons, but after some time, when they knew a bit more about it, they liked it. Because then they could identify the most common plant families, they had a feeling of success. My strategy was to start in small portions – each beginning of the lesson one family was presented, for the rest of the lesson we did another topic; for each plant family two of the students prepared a presentation and a poster – the posters stayed in the classroom. Thus they learned it in small doses.”* (post-§72 & 76). Within his fruits project he also connected several PCK components more closely in taking more responsibility for the learning and the interests of the students, with the curriculum in mind and with his confidence that he can build on their special abilities and interests: *“During the project I included other topics as well, which would have come later this year, but the students asked questions about them. For example, photosynthesis and plant morphology to get to the point that they could explain ´Where does the sugar in the rose hip come from?´. Another example is chemical testing for the substances fat, sugar and starch in seeds. This would not be possible with other kids, but with the high achievers I could try it.”* (post-§102).
PCK-development of Bert: His self efficacy was developed and moved into his focus and was also more closely connected with two other components after the PD course: KSUS & KSC! This development was already implicit in the pre-interview, but during the course Bert got to know the PCK model by Park & Oliver (2008), presented by the teacher educators as a grid for reflection on the project: “*As a novice teacher I was tortured to formulate the aims for a lesson - and what happens? You take the whole content and write it down e.g.´ text book p 27-29´. With this [PCK] grid it is not enough to state ´the student has to know what a stone fruit is´, but the aim is something higher-ranking and this is reflected in the six [PCK-] components. You become more conscious about why you teach this topic and in what sequence…*“(PCK discussion-§31). At the end of the post interview he explicitly said that SE is a PCK component which helps him teach biology: *“...some topics are important to me and the curriculum and so I insist on teaching them, I explain to my students’ why I do so and help them to work on them…”* (post-§150).

Anna

Subjective theory of Anna: A good relationship with the students is most important for her, biology content is important as well. Her lesson preparation happens last minute; in her biology class the topic is elaborated in a teacher-student-conversation, where questions and interests of her students are very important. She gives assignments only to grade her students. She likes being a biology teacher very much but she is not satisfied with her preparation style and the stress resulting from her curriculum delay at the end of the school year.
Results from the pre-interview: In the following quotation all the points of Anna’s characterization aggregate: “*At the end of the school year I have to rush through the topics that are necessary for completing the state curriculum. When I tell my students, that I will have to advance fast, they frequently ask me, ´Are you really sure that you will make it? ´.*“ (pre-§52). Self efficacy (SE) is represented in the intense relationship with her students; this is the basis for her teaching and is connected with her perception of her students; her guiding aim is: Students should not lose interest in biology; immediate learning of one topic is less

important for her. Therefore assessment is only done with the purpose of grading: *"Effective testing is done by me only when I have to do it."* (pre-§46). Her answer to the question about a teaching sequence she is really satisfied with was the following: *"It upsets me that I cannot recall any situations that I'm 100% proud of. All I remember is a sequence about spiders in the context of a PD seminar, where I had to work on all aspects during planning, because I had to teach biology in English."* (pre-§12). She mentions that this was nearly a perfect sequence because she was forced to plan ahead, also because the colleagues of the PD course and her headmaster would attend the lesson. In describing the learning of the students in this example she goes into great detail, connecting several PCK components like KSUS, KISR as well as SE. Moreover, assessment (KA) also turned up in an informal way: *„I had enough time to work with a comic I had prepared as an additional activity. The students were asked to identify mistakes and they did not only find the most obvious things, but also details e.g. that the spider was drawn like an insect with three major body parts instead of two. They looked very accurately and I was really satisfied with these results."* (pre-§12). During the PD course she was not able to conduct a project. She just developed material for observing the behaviour of mallard ducks with the focus on behavioural ecology in the tradition of Lorenz (1978). But even this material was only developed because she promised a colleague in the course to do so: *"We built a group [in the PD course] and wanted to develop something in behavioural ecology. We did so by sharing work; therefore I had the moral pressure to deliver the working sheets. Otherwise I would not have made it."* (post-§18).
Results from the post interview: She was not satisfied with a joint curriculum project with chemistry and physics on water quality of a creek in the pre interview and this was still the case in the post interview. She complained about the routine which made this course boring for her and her colleagues: *"You cannot avoid losing your enthusiasm if you present a topic again and again. And this is transferred to your students."* (post-§106). During the PD course we offered a fictitious story about a small hydropower plant to embed our field work at the creek and she claimed that this was a good idea. Once again she stated that she wanted to include this idea, but in the meantime she missed two chances to improve her water curriculum: "*...I want to implement this idea which we had in the PD course. I really liked it, when you embedded the analysis of the creek in this story about the potential for a hydro power plant. We should introduce such ideas; ..."* (post-§100). The PCK component SE was displayed identically in the post interview, all aspects could be reproduced. This is also the case in other aspects, for example, her stress with the lesson preparation: *"... It happens to me in my preparation, that – even when I start planning early – writing down the material is done only last minute."* (post-§50).
PCK development of Anna: In both interviews the SE was very important and her prominent PCK component; It includes the good relationship with her students; the other components are first of all linked to SE. She makes the importance of this component explicit: " *... Efficacy is the most important point for me - what is my mission? Then, the rest of the [PCK] components nearly filled in by themselves and afterwards the connections [between the categories] can also be seen. This is very helpful for planning and reflecting my lesson."* (PCK discussion-§2). This quotation from the PD course reflects her discovery of this component in working with PCK within the PD course. From this category onward she started planning her lesson and was overwhelmed by the result. But in the post interview it turned out that she had not transferred this strategy to her everyday work. She still reports about being dissatisfied with her preparation. Therefore no PCK development could be detected.

DISCUSSION & OUTLOOK

One teacher did develop PCK, the other one did not. Self efficacy played an important role for the development of PCK in these two cases even if it is an antithetic role. Bert, who developed both PCK and stronger connections between the components, planned and conducted a project with self efficacy as an important PCK category for himself in mind. In his case, self efficacy was the trigger to develop the PCK. Bert had already been aware of the changes over the years, reported his self efficacy in the pre interview, and mentioned it explicitly in the post interview, after introducing the PCK concept. This is expressed in the development and the fact that he does no longer suffer from the stress of completing the class curriculum within a year but can work on important concepts, knowing that he can build on them later on (connection between SE, KSUS & KSC). This strong connection was detected only in the post interview and was argued by him in several examples. He took the responsibility for helping the students to learn a topic. This aspect is in line with several authors: The consideration of the KSUS is a clue for developing PCK (e.g. Hashweh, 2005; Van Driel & Berry, 2010; Van Driel, Verloop, & Vos, 1998). Anna, on the other hand, did not conduct a project; therefore no practice with the given topic took place. This also restricted her reflection to the development without the teaching experience. In her case the self efficacy is a central component as well, but it seemed to hinder any development because in relying on her relationship and constructing her instruction around this factor, she had not felt the need to follow new paths. She has an elaborate content knowledge at hand, and therefore does not need a precise lesson plan but can start with a topic right away. As long as this relationship to her students and to the topic is not disturbed (e.g. by curriculum demands or assessment needs) she is very satisfied, also in reaching her personal goal (not loosing interest and some students should decide for a science or medical career) and in meeting the interests of her students. No development could be detected, although she was given matching offers to her self-reported problems.

Therefore we could prove the claim of Park & Oliver (2008) that SE is a central new component of the hexagon model of PCK. But teacher educators have to be aware of the complex interaction between the PCK components and their very different influences on each other. In comparing these two cases, reflected practice was the difference, and therefore provides a hint why Bert developed PCK and Anna did not. Further research on the role of the single PCK components in dependence on each other has to be done – to further develop the PCK model as such as well as to understand the potential for developing PCK in teacher education. One idea about the role of self efficacy is that SE is the antipode of the component teacher's orientation to teaching the subject (OTS). While OTS represents the teacher's beliefs to the school subject and the discipline itself; self efficacy is a kind of moderator component how the teaching is realized. Further research on this question has to be done.

DEVELOPING NETWORKS TO SUPPORT SCIENCE TEACHERS WORK

Martin Krabbe Sillasen[1] *and Paola Valero*[1]

INTRODUCTION

In educational research literature the concept of network has emerged as a strategy to support teachers' professional development (Huberman, 1995; Jackson & Temperley, 2007; Van Driel, Beijaard, & Verloop, 2001). This paper reports on a study about teachers' collaboration in networks on improving the quality of their own teaching practices. These networks exist at the meso-level of the educational system between the micro-realities of teachers' individual practice and the macro-level, where educational policies and intentions in the educational system are formulated. At this level networks provide an organizational frame where individual teachers' private knowledge and the public knowledge in the educational system can mix with the intention of improving teachers practices (Lieberman, 2000). The research question that guided this study is: How can networks provide opportunities for teachers from different schools to collaborate on improving the quality of their own teaching practice?

The context in which these networks were studied was a development project that was co-funded by the Danish Ministry of Education and four municipalities. The aims were to develop collaborative activities in primary science teacher communities in schools and in networks between teachers from different schools in each municipality. Each network were organized and moderated by a municipal science coordinator.

ANALYTICAL FRAMEWORK

The concept of *Network Learning Communities* (Jackson & Temperley, 2007; Lieberman, 2000; Stoll, Bolam, McMahon, Wallace, & Thomas, 2006) was used to analyze possibilities and constraints of network activities that aimed to improve participating teachers' individual practice. A characteristic feature of successful and sustainable networks is that the knowledge base balance between the private knowledge of the teachers and the public knowledge that informs the teachers practice through collaborative activities in the network (Busch & Sølberg, 2004; Jackson & Temperley, 2007; Lieberman, 2000; Lieberman & Wood, 2002).

RATIONALE

A statistical study aimed at, amongst other, estimating the effect of network communities on pupils outcome support the hypothesis that pupils do better in schools where teachers collaborate in networks (Jackson & Temperley, 2007). Similar findings is documented in the German SINUS-project, where pupils from schools participating in the SINUS-programme scored higher in PISA 2003 compared with pupils from schools not participating. A characteristic feature of the activities in SINUS is that communities of teachers from different schools collaborate in clusters about collective activities that aim at improving teacher collaboration, teachers' individual practice and sharing best practice (Ostermeier, Prenzel, & Duit, 2010)

Standard professional development programs are problematic, because they of deliver “one size fits all”-activities that are not easily adaptable to teachers own practice. On the other hand, networks provide the organizational framework that is highly user driven around the interests and needs of the participants (Lieberman, 2000); (Lieberman & McLaughlin, 1992). In their review on strategies to reform science education Van Driel et al (2001) claim that *learning in network* is a powerful strategy to achieve lasting change in teachers’ professional knowledge. Two arguments support this claim. First, experienced teachers’ natural resistance to innovation and change can be reduced by learning in networks. Second, learning in network may be particularly effective, when teachers share similar tasks, but have different experiences performing these tasks in their own school. Coming together to share knowledge provide opportunities for teachers’ to review different practices and develop a shared attitude about best practice.

METHOD

In the present study municipal science coordinators were asked to write narratives about network development in their municipality. This provided the researchers with four different accounts on network development. Their written narratives were then condensed into descriptions of the development of networks at the municipal level that provided information about possibilities and constraints for developing networks. The narratives outlined both activities, interactions between different stakeholders (municipal science coordinators, teachers, other resource persons and the municipality) and the overall progress during the three year time span of the development project. Then the researcher supplemented the narratives with interpretations about what elements that facilitated or constrained the development of networks. To increase validity the narratives with the researchers’ interpretation were the read by the municipal science coordinators and the revised and edited according to their suggestions. The narratives provided rich information about diverse conditions for developing networks. Diversity of the narratives was seen as a quality because of the explorative nature of the study.

In the next step the narratives were analyzed for patterns in elements that facilitated or constrained the development of networks. The first author then asked the municipal science coordinators to co-interpretate the patterns that had emerged in the narratives. Thus the municipal science coordinators contributed to a deeper understanding of elements that facilitated or constrained the network development (Kvale, 2004).

The written narratives were triangulated with two additional sources of information. The participating teachers’ response to a longitudinal survey and the assessment report that each school submitted when the development project ended. These data sources provided information from the teachers’ perspective about their attitude towards teacher-to-teacher collaboration within their own school, in network activities between schools and the municipal support in the networks. The longitudinal survey consisted of a questionnaire that was distributed at the beginning and end of the development project. It contained both closed and open-ended questions. Teachers’ responses to closed questions were subject to a statistical analysis. Differences between their initial and final responses were tested for significant variations by using t-test. The responses to open-ended questions were categorized according to whether the teachers expressed a positive, neutral or negative attitude about teacher-to-teacher collaboration, network activities and municipal support. The assessment reports that each school submitted at the end of the project were collective accounts from the group of teachers participating in the project. The assessment was guided by open-ended questions and the responses were categorized similarly to the individual teachers’ responses to the open-ended questions in the longitudinal survey. For details about these two sources of information see the technical report (Sillasen & Valero, 2011).

RESULTS

The study revealed several elements that facilitated a sustainable development of teachers' collaboration in networks.

One element was the recruitment of an experienced science teacher to guide teachers in their collaborative activities both within the schools and in network activities. For some network groups the guidance of an experienced science teacher was of great value to inspire the teachers on developing new activities.

A second element of the network was the biannual workshops where teachers from different schools came together to engage in collective activities. In one municipality the science coordinator had chosen outdoor education as a common theme for development of teaching activities. In the municipal workshop an external resource person supported the teachers in their collective effort to develop teaching activities using the framework of outdoor education.

A third element of the network was the creation of network groups of particular interest. One example is from a municipality in a rural district with many small schools. In one of the municipal workshops teachers from these small schools met and formed the "rural schools network". In the assessment report from one of these rural schools teachers wrote that "the rural schools network" *was a very fruitful community, because all teachers in the network shared similar conditions and challenges in teaching science.*

A fourth element was the participation of the municipal science coordinators in network formation. The municipal science consultant's participation in network activities was multifunctional. S/he communicated with schools about what their needs are for external support, planned collective activities, invited external actors, organized workshops, applied for funding for network activities, found examples of good practice within the network that could be shared and coordinated local support for schools and network activities. An important personal competence of these municipal science coordinators was to be highly adaptable to the needs and demands of the participating teachers in the network. Their participation at various levels of the network activities was highly valued by the participating teachers.

The study also provided examples of network activities that constrained sustainability of the network. One important element was that the collaborative activities must relate directly to teachers daily practice. Otherwise there was a risk that teachers did not feel obliged to engage in future network activities. A second element was that the network needs a dedicated moderator to coordinate, communicate and recruit teachers to engage in network activities. A third element was that the moderator needs support from the municipality or a local science centre to sustain the network. Otherwise the moderator might feel declined to continue network moderation if the network was not institutionalized.

CONCLUSIONS

The research presented here shows that developing networks provide opportunities for teachers to come together to share knowledge about their individual teaching, to be inspired by external resource persons and to commit to developing new teaching activities in collaboration with teachers from other schools. But the sustainability of these network activities depended strongly on whether the teachers considered the outcome to be useful in their own teaching practice. Second, developing networks is a fragile process that requires commitment from various levels of the educational system (teachers, municipal science coordinators, school leaders and science centers).

IN-SERVICE SCIENCE TEACHERS' TECHNOLOGICAL PEDAGOGICAL CONTENT KNOWLEDGE CONFIDENCE LEVELS AND VIEWS ABOUT TECHNOLOGY-RICH ENVIRONMENTS

Mehmet Fatih TAŞAR[1] *and Betül TİMUR*[2]
[1] Gazi University, Science Education Department, Ankara, TURKEY
[2] Çanakkale Onsekiz Mart University, Science Education Department, Çanakkale, TURKEY

Abstract: Science teachers need to be able to integrate technology into science teaching. Identifying science teachers' confidence levels in technological pedagogical content knowledge (TPCK) and determining their views about using TRE in science instruction is an important issue since it can reveal if and how they will use TREs. Therefore, this study aims to address challenges faced by in-service science teachers during creating TREs. The data were gathered through the TPCK confidence survey and subsequent interviews. Ninety-five in-service science teachers from public middle schools in Ankara participated in this study. Additionally, interviews were conducted with four voluntary participants. Findings showed that in-service science teachers had a low level of confidence in using technology in science teaching and they stressed that they need professional development for using TRE for effective and meaningful science teaching.

Keywords: Technological Pedagogical Content Knowledge, Teacher Confidence, In-Service Teachers, Technology-Rich Environments

INTRODUCTION

The turn of the 21st century marked the beginning of a much common and widespread use of computer technologies in science classrooms and practically everywhere else because personal computer hardware with even higher capacities became affordable to larger populations and applications with enhanced visual characteristics were created with lesser effort not only by computer experts but also by science educators. Although not sufficient for all teachers, several initiatives and efforts emerged in order to help science teachers to better understand associated teaching methodologies and benefits of Technology-Rich Environments (TRE) in science.

Knowledge of the natural sciences is connected to explain objects, phenomena, and their interactions in the natural world (Lunetta, Hofstein, & Clough, 2007). Therefore, learning about nature should take place through interaction (careful observation, manipulation, and drawing conclusions) with the phenomena and not in an abstract way. The constructivist approach to teaching and learning stresses that learners are not blank slates on which to write freely. Rather they come to the learning environments with all sorts of pre-conceptions and these are often times are not scientifically acceptable. Science teachers as facilitators of learning in classrooms design meaningful learning activities and environments in which students can gradually construct an understanding compatible with the scientifically acceptable ones.

Hence, science instruction should help them "(a) add powerful, durable, and generative examples to their repertoire of ideas; and (b) enable students to grapple with their full repertoire of ideas to form a more coherent perspective on the scientific domain. Technology-

enhanced materials that make scientific thinking visible can play an important role in both processes" (Kali & Linn, 2008).
In the coming years, computing is expected to be increasingly effective and unavoidably necessary in the processes of science as it is expressed in "Towards 2020 Science" report: "Scientists will need to be completely computationally and mathematically literate, and by 2020, it will simply not be possible to do science without such literacy. This therefore has important implications for education policy right now" (The Science Group, 2006, p.8). In an OECD report entitled "21st Century Learning Environments" the role of schools are specified as follows: "Today, ICT skills – from completing a simple search on the Internet and writing an essay in Word, to cutting a video and designing a Web page – are a prerequisite for entry into the workforce. Schools have an important role to play in providing students with the necessary skills to become tomorrow's knowledge workers" (OECD, 2006, p.20). In-service science teachers play an important role in creating successful Technology-Rich Environments (TRE) in science teaching and their TPCK confidence is an effective factor to create technology rich science teaching environments

Science teachers' technological pedagogical content knowledge

Technological pedagogical content knowledge (now known as TPCK or TPACK) has become a commonly referenced conceptual framework of teacher knowledge for technology integration within teacher education. TPCK is described as complex interaction of content, pedagogy and technology and discussion of successful integration of technology into instruction (Koehler & Mishra, 2008). In recent years researchers described TPCK within the framework Shulman's (1987, 1986) description of pedagogical content knowledge (PCK). According to Shulman (1986, p.9) PCK "goes beyond the knowledge of subject matter per se to the dimension of subject matter knowledge for teaching" and PCK is the connection and relation of pedagogy and content knowledge. Researchers conceptualized PCK in the domain of teaching with technology under different schemes: "Margerum-Lays and Marx (2003) referred to PCK of educational technology, Slough and Connell (2006) used the term technological content knowledge, and Mishra and Koehler (2006) suggested the term technological pedagogical content knowledge (TPCK) – a comprehensive term that has prevailed in the literature" (as referred to and cited in Angeli & Valanides, 2009, p.155). TPCK can be described as how teachers understand educational technologies and PCK interacts with technology to produce effective teaching with technology.

Aim of the Study

This study aims to measure in-service science teachers' TPCK confidence and identify their views about using Technology-Rich Environments (TRE) in science and also we aim to address challenges faced by in-service science teachers creating TRE, give suggestions for successful technology integration in science teaching.

Research questions

This study will focus on the following research questions:

I. What are in-service science teachers' confidence levels on four TPCK constructs (i.e., TK, TPK, TCK, TPCK)?
II. What are in-service science teachers' views, needs, and classroom practices about Technology-Rich Environments?

METHODOLOGY

A non-random purposeful sample was used to gather data from in-service science teachers. Ninety-five voluntary public school science teachers participated in this survey. Both quantitative and qualitative research methods were used to investigate the level of TPCK confidence. The TPCK confidence-science instrument has been adapted into Turkish from Graham, Burgoyne, Cantrell, Smith, Clair and Harris (2009). The instrument was sent to more than 450 in-service teachers by e-mail. 101 teachers' completed and returned the survey, but 6 of them were excluded because of missing data. Additionally, face to face semi-structured interviews were conducted with 4 of the participants. Sample characteristics are summarized in Table 1.

Table 1. The characteristics of participants

The characteristics of participants	f	%
Gender		
Female	44	46.3
Male	51	53.7
Teaching hours in a week		
10-14	10	10.5
15-19	35	36.8
20-24	38	40.0
25-19	10	10.5
29-34	2	2.1
Number of Students in teachers' classroom		
Less than 20	10	10.5
Between 21-30	60	63.2
Between 31-40	21	22.1
Between 41-50	4	4.2
Teachers' Professional Experience		
1-5 years	17	17.9
6-10 years	35	36.8
11-15 years	23	24.2
16-20 years	13	13.7
Upper than 21 years	7	7.4

RESULTS and DISCUSSION

To address the question of perceived confidence level of in-service science teachers' related to the four TPCK constructs teachers were asked, "How would you rate your own confidence related to task associated?" Twenty-four items along the areas of technological knowledge, technological pedagogical knowledge, technological content knowledge, and technological pedagogical content knowledge of these areas were asked, and the scale for answering consisted of 5 points of confidence. Means were calculated for all items is showed in table 3 and average mean for four sub-factors is showed in table 4. Table 2 shows the ranges of confidence levels formed.

Table 2. The Ranges Belonging Confidence for Likert Type Scale

Range Value	Confidence Level
1,00–1,79	not confident at all
1,80–2,59	slightly confident
2,60–3,39	somewhat confident
3,40–4,19	fairly confident
4,20–5,00	completely confident

From the responses of teachers' ranges, minimum, maximum and standard deviation are reported for each item. TPCK sub-factor teachers asserted that they feel somewhat confidence in the 6th item "Help students use digital technologies to organize and identify patterns in scientific data", TPK sub-factor they feel somewhat confidence in 4 items "Help students use digital technologies that extend their ability to observe scientific phenomenon", "Help students use digital technologies that allow them to create an0d/or manipulate models of scientific phenomenon", "Use digital technologies to improve communication with students", "Use digital technologies to help in assessing student learning". All items of TCK sub-factor, teachers asserted that they feel somewhat confidence and TK sub-factor “Create and edit a video clip” item they feel somewhat confidence but two items “Use Web 2.0 technologies” and “Create your own website” they feel slightly confidence.

Table 3. Summary of Descriptive Statistics Results for the Question, "How Would You Rate Your Confidence in Doing the Following Tasks Associated With Technology Usage?"

SF	Item	N	Range	Minimum	Maximum	Mean	Std. Deviation
TPCK	4	95	4,00	1,00	5,00	3,66	,918
	5	95	4,00	1,00	5,00	3,42	1,03
	6	95	4,00	1,00	5,00	**2,97**	1,18
TPK	7	95	4,00	1,00	5,00	**3,03**	1,11
	8	95	4,00	1,00	5,00	**2,84**	1,27
	9	95	4,00	1,00	5,00	3,52	1,10
	10	95	4,00	1,00	5,00	**3,14**	1,13
	12	95	3,00	2,00	5,00	3,51	1,03
	13	95	4,00	1,00	5,00	3,76	1,02
	14	95	3,00	2,00	5,00	3,42	,917
	15	95	3,00	2,00	5,00	**3,35**	,921
TCK	16	95	4,00	1,00	5,00	**3,23**	1,04
	17	95	4,00	1,00	5,00	**3,10**	1,18
	18	95	4,00	1,00	5,00	**3,03**	1,19
	19	95	4,00	1,00	5,00	**3,30**	1,04
	20	95	4,00	1,00	5,00	**3,21**	1,08
TK	21	95	3,00	2,00	5,00	3,90	,911
	22	95	3,00	2,00	5,00	4,22	,865
	23	95	3,00	2,00	5,00	3,70	1,20
	24	95	4,00	1,00	5,00	3,96	1,06
	28	95	4,00	1,00	5,00	3,52	1,25
	29	95	4,00	1,00	5,00	**2,77**	1,48
	30	95	4,00	1,00	5,00	**2,10**	1,283
	31	95	4,00	1,00	5,00	**2,25**	1,20

Table 4. Summary of Descriptive Statistics for Sub-factors for the Question, "How Would You Rate Your Confidence in Doing the Following Tasks Associated With Technology Usage?"

				Scale		**Item**	
Sub-Factors	Number of Items	Min.	Max.	Mean	Std. Deviation	Mean	Std. Deviation
TPCK	3	3,00	15,00	10,06	2,77	3.53	.92
TPK	8	12,00	40,00	26,61	7,35	3.25	.92
TCK	5	5,00	25,00	15,88	4,98	3.18	.99
TK	8	12,00	40,00	26,46	7,38	3.31	.92

From the responses of teachers, they asserted that they feel fairly confidence TPCK sub-factor but somewhat confidence TPK, TCK and TK sub-factors. Teachers feel least confidence TCK sub-factor items that mean they cannot use the educational technologies for a specific topic and get difficulties while relating technology and content, in their science instruction. Vice versa, they feel somewhat confidence knowledge about how to use technology and also to teach more effectively with technology, help students meet any specific curriculum content to use technologies appropriately in their learning. “In other words, merely knowing how to use technology is not the same as knowing how to teach with it" (Mishra, & Koehler, 2006). Teachers feel most confidence in their ability when teaching science with technologies (TPCK) (Graham et al, 2009).

The second research question was "What are the in-service science teachers' views, needs, and classroom practices about TRE?" in order to find an answer to this question 5 questions were asked to 95 in-service science teacher and semi-structured interviews were conducted with 4 teacher

Table 5 Descriptive Statistics of Teachers' Views about TRE in Science

Computer facilities	f	%
Computer facilities at the school		
None computer at school	6	6.3
One computer each class	28	29.7
Computer Lab. at school	41	43.2
One computer used for several class	20	21.1
Hours in a week computer-based instruction		
1	17	17.9
2	33	34.7
3	17	17.9
4	11	11.6
More than 4	17	17.9
Group of class in computer-based instruction		
One computer each student	5	5.3
One computer for two students	8	8.4
Small groups	11	11.6
Whole class	71	74.7
Computer based instruction years		
0	10	10.5
1-5	72	75.7
6-10	13	13.8
Need professional development using computer for instruction in science		
Yes	74	77.9
No	21	22.1

Responses to the questions about TRE teachers asserted that computer facilities at their schools are not well enough to create a TRE so they generally give computer-based instruction to whole class and approximately all the teachers need a professional development about how to use the computers in science instruction. There is a need for providing technological pedagogical content knowledge confidence to in-service science teachers in order to create optimally functioning technology enhanced classrooms. Some recent studies focused on the barriers effecting technology integration such as limited access to internet, classroom size, and lack of teachers' knowledge about successful technology integration into instruction (Çakır & Yıldırım, 2009; Cure & Özdener, 2008). Also some other researches indicate that PD program have positive impacts to on teachers' development of TPACK (Guzey & Roehrig, 2009; Graham et al. 2009; Varma, Husic & Linn, 2008) and can help teachers successfully, integrate technology into their practice (Niess, 2005; Harris, Mishra & Koehler, 2009).

Interviews were conducted with 2 male and 2 female science teachers. Four questions were asked in order to understand how they create a TRE in science instruction. The following four questions were asked during the interviews:

i. For what purposes do you use computers in teaching science?
ii. What are the barriers to the TRE in teaching science?
iii. How do you currently use computers to support your science teaching?
iv. How do you create a TRE in science teaching?

Teachers asserted that they use computers for showing animations, simulations, watching videos, films, making representations with power point during their instruction. The barriers to TRE were; no access to internet at schools, difficult to find and do technology rich materials such as animations, simulations, video for every subject, creating TRE needs good planning and preparing before the class, having classroom management problems. Teachers tend to group TRE for whole class and show the animations, simulations, video by the projector. They asserted that they sometimes stop the video or animation and ask questions to the class about the subject. One teacher described current use of computers in his science instruction as follows:

> *I usually use animations or videos form instruction. It is difficult to find visualizations for every subject in science since most science subjects are abstract. I have to spend time and prepare in order to create technology rich science lessons. However, students in my class are highly motivated when I use visualizations in my science teaching. In the last lesson, I used a cartoon animation of blood cells in my class. The whole class watched the animation together and solved a puzzle after the animation. However, sometimes watching a video or animation in a science lesson cannot be different from watching a movie at the cinema.*

Another teacher described her technology rich class as follows:

> *I use a projector when I am using computer in my class. I arrange student's seats in the best way for them to see the whiteboard. I start the lesson with brainstorming about the subject then we watch a video or animation. I do not usually have classroom management problems because students are highly motivated when they are watching a video or animation. However, sometimes students find their peer's questions ridiculous or foolish*.

CONCLUSION

This study shows that in-service science teachers do not have TPCK confidence sufficient to create a TRE in science teaching. They need professional development about how to use TRE in science teaching. Teachers need to have confidence to use technology as enrichment not as a replacement in science teaching. Koch (2005, p.25) emphasizes that technology cannot alone help students learn science. As she explains a computer can become a part of the science learning experience, if the child feels a need to use it in learning and such a need can be created for example while exploring what causes different weather conditions. In this case students can easily access to some weather reports from the Internet. This act makes the computer a useful and meaningful tool in learning. Such use can also be found in many other computer applications (e.g. certain software packages and online resources) that allow students to explore science phenomena in a simulated environment. Access to interactive manipulation of the simulated phenomena, in a way, forms a science laboratory that allows the child to study and learn in her/his convenience. Successfully integrating technology into science education heavily relies on the development of well-built, coherent professional development programs that are designed with a clear understanding of how teachers need to use technology in their class in the most effective way.

INTEGRATING TECHNOLOGY INTO PRE-SERVICE PHYSICS TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE

Hildegard Urban-Woldron[1]
[1]University of Vienna

Abstract: New physics teachers should be equipped with competences for successful integration of technology in the classroom. As an extension of Shulman's PCK (Pedagogical Content Knowledge), teachers need to learn how technological tools can transform pedagogical strategies and content representations for teaching specific topics. The paper reports on the integration of selective teacher training materials, which were used through a blended learning course for pre-service physics teachers. Focusing on the development of Technological Pedagogical Content Knowledge (TPACK) the study examines how pre-service teacher candidates used computer-based technology, to enhance their lesson plans, by selecting appropriate technology tools from the course materials of a European funded project and creating learning opportunities for students. The pre-service candidates' questionnaires, lesson plans and reflection journals were sources of data. Data were analyzed, incorporating both quantitative and qualitative techniques, to determine the effectiveness of the course materials and the course design on pre-service physics teachers' development of TPACK. The training materials appear to stimulate pre-service physics teachers' thinking about useful instructional technological strategies and helped in promoting the development of their Technological Pedagogical Content Knowledge. The findings of the study highlight a need for future research on the development of teachers' TPACK.

Keywords: Pre-service physics teachers, computer-based technology, integrating technology, development of TPACK, blended learning course

THEORETICAL BACKGROUND

Research literature on computer-supported learning suggests the consideration of two important aspects. Firstly, due to the diversity of disciplines and unique features of technology, the ways in which technology might best be used for each discipline strongly depend on the content to be taught [3]. Secondly, the extension of Shulman's concept of "pedagogical content knowledge" to "technological pedagogical content knowledge" (TPACK) [7] emphasizes the critical role of the teacher as curriculum designer. It follows that realizing the potential of the technology requires skills not just of technology, pedagogy, and content in isolation but rather of all three taken together. TPACK is primarily achieved when teachers know how technological tools can transform pedagogical strategies and content representations for teaching specific topics [6].

According to the conceptual framework of Sandholtz, Ringstaff & Dwyer [9] teachers have to move through an evolution of thought and practice when learning to use technology in the learning process. They should start in the so-called 'entry-phase' and end up in the 'invention-phase' discovering new uses for technology tools and using technology as a flexible tool in the classroom to facilitate the emergence of new teaching and learning practices. At a typical entry-level, the teacher uses direct instruction and whole class activities to deliver content and skills to the students. In a classroom of a teacher at innovation (or invention)-level, students are engaged in using technology to do things that could not be done without it.

Researchers and practitioners have been seeking reliable and valid ways to measure the constructs associated with the TPACK framework. Harris and her colleagues [4] promote in amendment of published self-report surveys for assessing TPACK an instrument that supports a performance-based evaluation of TPACK, enabling a triangulation of self-report data and external assessments. Their “TPACK-based technology integration assessment rubric” should support teacher educators to more accurately assess the quality of technology integration in their students’ lesson plans by reflecting on four dimensions: Curriculum-based technology use, using technology in teaching/learning, compatibility with curriculum goals & instructional strategies, fit of content, pedagogy and technology together.

RATIONALE

Recent reviews of the effects of ICT in science lessons show that teachers do not yet exploit the creative potential of ICT and do not engage students enough in the production of knowledge [1]. Therefore teachers need training and continuing professional development in the use of ICT to carefully integrate ICT into the teaching process and to provide appropriate guidance [5]. Actually, ICT-rich environments already provide a range of affordances to enable learning of science [11]. Researchers suggest that integrating these affordances with other pedagogical innovations provides even greater potential for enhancement of student learning [2]. Therefore, supporting the professional development of pre-service teachers for technology integration seems to be an important issue for teacher education.

The context of this study was a teacher education course, aiming at helping prospective teachers to develop abilities to integrate technology with content and pedagogy. Teaching materials developed within a European project and adapted for the education method course, covered three different physics topics: “Cooling & change of state”, “basic electricity concepts” and “motion & forces”. For each topic, up to three types of activities, exploiting the use of ICT to stimulate thinking and promote understanding of basic physics concepts, were offered: Data-logging, simulation and modelling.

The purpose of the study was to investigate prospective teachers’ development of TPACK attempting to address two broad questions:

1. Is there a relationship between the perceptions of the learning environment, motivational orientations and the self-reported evolution of TPACK?
2. Are self-reported knowledge gains in TPACK in agreement with external assessment of teachers’ own lesson plan designs?

METHOD

Participants and Setting

The participants of the study included 17 prospective teachers (9 female, 8 male); all were novices in the field of technology integration in physics teaching and learning. The course was designed as blended-learning course lasting 16 weeks throughout a whole semester. For communication and collaboration as well as for the distribution of the training materials and the questionnaires an electronic platform, based on the software Moodle, was used. There were three 4-hour in-class units in the weeks 1, 6 and 10, during which the prospective teachers were offered opportunities to learn from and not about teaching with technology (see table 1). By means of self-study materials, prospective teachers had to work on individual assignments, designing lesson plans for each of the three topics (cooling & change of state, basic electricity concepts, and motion & forces), and deliver them to the instructor. The elearning-part of the course enabled prospective teachers to share and discuss their ideas.

Week	Components	Methodology
1	Class session introducing data-logging activities	The initial class session introduced data-logging activities (analysing motion, free fall, accelerated trolley, rebounding trolley and current and voltage for a tungsten bulb) with opportunities for practical work resulting in collecting data.
2 - 5	Individual assignments using on-line resources for video and data-logging	In the succeeding weeks students worked autonomously, obtaining the module and software resources through the *Moodle Virtual Learning Environment (*VLE). Through self-study, students learned to analyse video capture data and then chose a topic for which they were required to design a lesson plan featuring the use of video measurement or data-logging.
6	Class session introducing modelling activities	In the second class session, students were introduced to modelling activities featuring the same topics as the first data-logging session.
7 - 9	Individual assignments using on-line resources for modelling	During weeks 7 to 9, students engaged in a further self-study assignment concluding with designing another lesson plan on a chosen topic. This time students were also expected to communicate with each other through the forum within the VLE, exchanging ideas and comments on each other lesson designs.
10	Class session	The third class session introduced simulation activities from the chosen modules.
11 - 14	Individual assignments	During the next weeks of self-study, students engaged in a third lesson design assignment on a chosen topic, exchanging ideas through the VLE forum as previously.
15 - 16	On-line discussion	In the final two weeks students were required to use the VLE forum to discuss with colleagues the potential learning benefits of integrating the ICT activities into physics teaching.

Table 1. Components and methodology of the course

Data Sources

The scales and items for assessing prospective teachers' motivational orientations and their perceptions in TPACK domains were primarily drawn from literature [8; 10] and accordingly adapted. A motivation questionnaire was administered in week 1, whereas a TPACK questionnaire was completed twice, as initial one and at the end of the semester. Additionally each of the participants of the study prepared a reflective journal on the overall process of the course at the end of the semester as well as three lesson plans at specified dates.

Data Analysis

Responses from the TPACK questionnaire were analyzed as matched-pair means for each survey question. The quality of technology integration was assessed by means of the

Technology Integration Assessment Rubric (see figure 1), which is based on the frameworks of Sandholtz and Harris and their colleagues [4, 9].

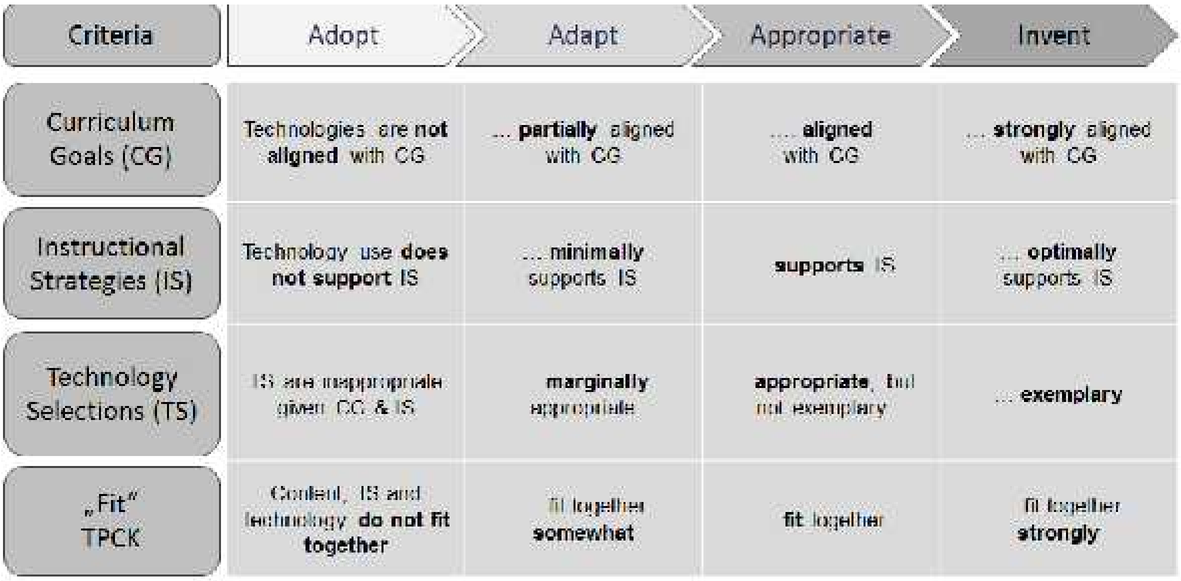

Figure 1. Technology Integration Assessment Rubric[1]

Also, the relationship among motivational orientations, perceived TPACK and pre-post-difference as well as the quality of TPACK inferred from the lesson plans was analyzed. As the primary method of data examination for the reflective journals and the open questions verbal inductive analysis was used. Accordingly, the data were assigned to four categories, resulting in a numerical overview of the outcomes. All items of the questionnaires were aligned on a Likert scale, ranging from 1, "I totally disagree" to 4, "I totally agree".
Also, the relationship among motivational orientations, perceived TPACK and pre-post-differences as well as the quality of TPACK inferred from the lesson plans was analyzed. As the primary method of data examination for the reflective journals and the open questions verbal inductive analysis was used. Accordingly, the data were assigned to four categories, resulting in a numerical overview of the outcomes. All items of the questionnaires were aligned on a Likert scale, ranging from 1, "I totally disagree" to 4, "I totally agree".

RESULTS

The findings of the study indicated that prospective teachers value the course materials as well as the design of the course to be helpful for developing a critical understanding of TPACK, independently from gender and motivational orientations. Prospective teachers' goals and value beliefs for the course seem to have a positive impact on the evolution of TPACK, both inferred from self-reports and the external assessment of the associated lesson plans.

A cluster analysis (see figure 2 and table 2) of the motivational scales shows that the participants of the study can be arranged to three groups: 29% (CL1) report high estimates for goal orientation, content task value, self-efficacy, and control of learning beliefs. Whereas

[1] Based on the conceptual frameworks of Sandholtz and Harris and their colleagues

47% of the students in CL 3 are confident in their abilities for accomplishing and performing the future tasks an report rather high values for control of learning beliefs, they are not so highly intrinsically, but more extrinsically, motivated and additionally, not convinced about the importance and usefulness of the course.

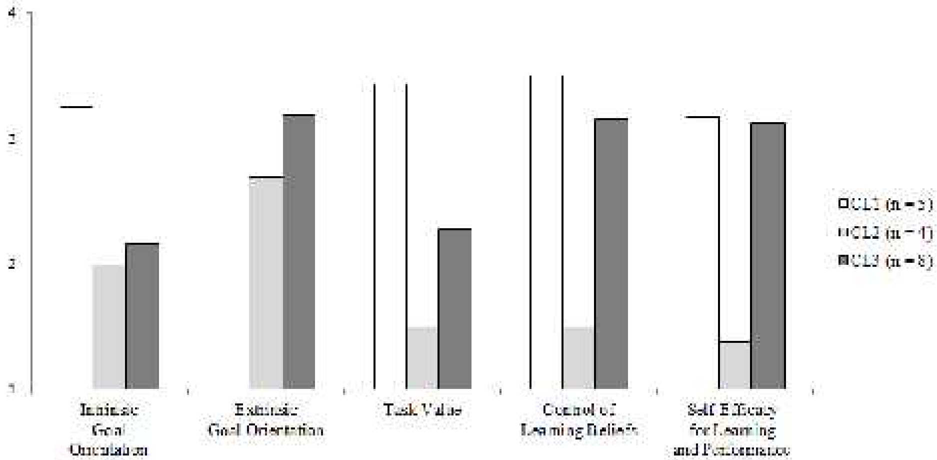

Figure 2. Motivational orientations of the pre-service teachers

24% of the students in CL2 can be described as students with motivational strategies clearly underneath the mean. They report considerable low estimates for their task value, their control of learning beliefs, and their self-efficacy for learning and performance. Furthermore, their ratings for intrinsic as well as extrinsic motivation are also significantly lower than the reference values of group CL3.

	M_{CL1}	SD_{CL1}	M_{CL2}	SD_{CL2}	M_{CL3}	SD_{CL3}
Intrinsic goal orientation	3.25	0,53	2.00	0.88	2.16	0.82
Self- efficacy for learning and performance	3.18	0.09	1.38	0.00	3.13	0.93
Content task value	3.43	0.17	1.50	0.00	2.27	0.94
Number of students	5		4		8	

Table 2. Descriptive statistics of motivational strategies

As illustrated in figure 3, there is also a relationship between motivational orientations and evolution of TPACK. The grey bars in figure 2 correspond to the pre-post-differences of perceived TPACK; the white bars represent the quality of technology integration derived from the lesson plans. The values illustrate the level reached in percentages of the maximum, related to four on the used Likert scales. For example, students in CL1 estimated their TPACK increase to 73% of the maximum and the quality of their lesson plans were rated to reach 67% of the maximum.

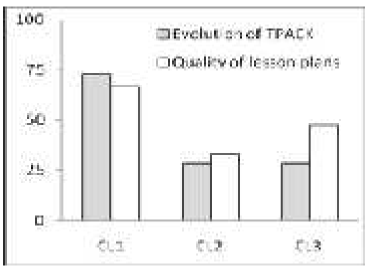

Figure 3: Evolution of TPACK

In addition, ANOVA (see table 3) shows that there is also a significant difference between the groups' mean scores concerning the quality of the corresponding lesson plans (F value = 10.399, significance value = 0.002). For example, students in CL1 attain 14 points on average out of a maximum of 16 points for their third lesson plans, whereas students from group 2 only reach a mean score of 6 points.

ONEWAY ANOVA

Mean Level of TPCK evolution					
	Sum of squares	df	Mean Square	F	Sig.
Between Groups	160.809	2	80.404	10.399	.002
Within Groups	108.250	14	7.732		
Total	269.059	16			

Table 3. ANOVA for the relationship 'affiliation to a certain cluster and quality of lesson plans'

CONCLUSIONS AND IMPLICATIONS

In conclusion, this study provides empirical evidence about the impact of the training materials and the course design on prospective teachers' TPACK in particular topics of physics subject matter. Thereby, the development of TPACK is closely related to the motivational orientations of the pre-service teachers. In consequence, it appears reasonable to focus both on issues to motivate pre-service teachers and on certain content topics for highlighting the pedagogical value of the specific use of technologies for understanding physics concepts.

In order to make future teachers capable to attach importance to their crucial role in the learning process of students, especially when ICT tools are introduced, the need for reinterpreting this role becomes an essential demand in teacher preparation programmes aimed at promoting the use of ICT. To provide vision of, how the teacher's role can influence the successful outcome of ICT activities in science education, should be a chief rationale of educational technology training courses. Indeed, before examining the principles underpinning the teacher's role, it is appropriate to review the potential learning benefits associated with the four software tools which serve constructional activities in physics: data-logging, modelling, simulation and video measurement.

However, there is a clear need for future research on how to best design teacher education programs in preparing future educators for the challenge of teaching in the 21st century. Teacher education programs should certainly focus on developing TPACK to enable teachers firstly, to identify their crucial role in using educational technologies in the classroom, and secondarily, to design computer-assisted learning activities which offer guidance as well as room for individual exploration. The teacher's role is critical in structuring tasks and interventions in ways which prompt pupils using ICT to think about underlying concepts and relationships and to find the right way of instruction and level of complexity. Therefore, future research programs should be aimed at both developing teachers' TPACK and evaluating teacher training programs by observing classroom activities and assessing student outcomes.

PART 14: EARLY YEARS SCIENCE EDUCATION

Co-editors: *Costas Constantinou and Jane Johnston*

Emergent science, science pedagogy and learning in the early years, cognitive resources for science learning, early years science and technology curriculum, innovative teaching practices in the early years, children's learning, preschool science, early years teacher education in science.

This part corresponds to strand 14. It contains 9 papers.

TABLE OF CONTENTS OF PART 14
EARLY YEARS SCIENCE EDUCATION

INTRODUCTION

In recent years early years science has emerged as a serious research focus in the science educational research community. This has occurred as a result of two paradigm shifts in science education. The first is a shift from a focus on the science – the concepts and skills of scientific inquiry, to greater focus on education – the pedagogical approaches that support scientific and holistic development. The second is a shift from a 'top down' to a 'bottom up' approach, with increasing recognition that early years science, that is, science for young children aged between birth and 8 years of age, is the foundation of all later development and is not well understood. In the European Science Education Research Association (ESERA) this has resulted in an increase of research papers focusing on early years and in 2011 the first Early Years strand. The papers in this chapter are the result of this and exemplify the variety and depth of research in early years science, both within Europe and further afield.

Despite the variety of research that is being undertaken in early years science, there are some common themes emerging in this collection of papers, which illustrate the current issues taxing early years professionals. Making science relevant and motivating for young children in science permeates all papers and indicates the dilemma that may educationalists face, whatever the age of the pupils; that is how to relate scientific conceptual learning to the everyday lives of children. There are a number of ways this is achieved in the papers. Story as a motivational force is a strong theme in four papers. In the early years, the link between the abstract and difficult concepts the teachers is hoping the children will learn can be achieved through the bridge between scientific knowledge and fiction. Other motivational forces are recognised as animals by Gkouskou and Koliopoulos who further look at the most effective pedagogical approaches to ensure that museum educational activities have a positive impact.

In the research involving story another common theme is the use of dialogue to discuss the scientific ideas in the fiction. This is another big issue in early years settings and is a theme also picked up by Kallery in her paper and she further identifies the importance of dialogue with peers. This type of dialogue enables children and teachers to learn together and is not cognitively restricting. The importance of pedagogical and assessment approaches that include elements of dialogic teaching are becoming increasingly recognised by early years professionals and this is another common theme between papers.

Overall, the papers cover a cross section of the issues that early years professionals face in teaching and supporting development in science with young children and the papers therefore are a useful and interesting contribution to the knowledge about young children's emergent scientific development.

Abstract: This work is part of the research FONDECYT Project 11100402 "Beliefs of Preschool Teachers Regarding Science, Science Teaching and Learning and their Influence on the Implementation of the Program YOUR COMPETENCES IN SCIENCES (YCS, TCC for its acronym in Spanish)" The purpose of this research is to identify and charaterize the beliefs of 61 preeschool teachers about sciences, its teaching and learning, to then study their development and influence in teacher's practices. The data were collected from an inventory of teachers' pedagogical and scientific beliefs (Porlán, 1997). Preliminary results show a relationship between the teachers' beliefs and certain science teaching-learning models of the teachers.

Keywords: beliefs, science teaching, preeschool education

BACKGROUND, FRAMEWORK, AND PURPOSE.

Belief and behavior appear frequently associated, and a great part of the definitions have in common that *beliefs* guide the thinking and action of people in an conscious and unconscious way and the individual accepts it as truth, and, consequently, it has an influence on in the emotional commitment, even more, it works as a guide for thinking, behavior, or attitude (Borg, 2001). The interest for beliefs lies in the fact that behind a teaching professional practice there is a belief or philosophy (Thom, 1973). A teacher is a reflexive, rational and decision-maker subject, he or she gives opinions, has beliefs and creates his or her own professional development routines, which has to lead indentify the proffesional knowledge of the science teachers and their epistemology to transform the curriculum and train science teachers (Perafán, 2005). This interest dates from the latest 80's, with studies focused on the image of science (Lederman, 1992, 2007), exploration of the concept of science (Porlán, 2004), learning (Aguirre, 1995), and curriculum (Porlán, 2004). Teachers' beliefs would reflect on their behavior or the attitude they show when facing their professional practice, and in this sense the theories of an elementary school teacher regarding science, teaching and learning have a great part in determining the scientific education a child gets. Referring to the same, Levitt (Levitt, 2001) says about preschool teachers that their belief systems are a main and determining factor of the decisions they made about their classes. From another perspective, McCarty et al (2001) reveal that educators whose classes were lower-quality were more likely to answer positively when suggested they had inappropriate practices that teachers with better-quality classes.

In Chile, there are great efforts to improve science education, for example, programs like "Your Competences in Sciences" (YCS, TCC for its acronym in Spanish) is an EXPLORA Program iniciative (http://www.tccexplora.cl/) that through informal workshops, seeks for the development and implementation of formative translation of science competences created for all-level students. Regarding the implementation of these workshops, the objective of the project is to identify the beliefs about science, teaching and learning in preschool teachers of the V Region of Valparaiso, and also, to determine to what extent they have influence on the implementation of their own model of science and the scientific activity it promotes (YCS). Nonetheless, in our country there are little empirical studies about sciences mentioned subject.

Rationale.

Research on the area suggests that this has to be conducted during the course of the class in order to be able to inquiry about which are the beliefs that are most influential on teaching (Lederman, 1992). Some preschool teachers may feel uncomfortable with their knowledge level about science contents, as a result, they may limit the role of science in the classroom (Diffily, 2001). As YCS is targeted to the development and implementation of the competences in sciences set for prescool students, we wonder which beliefs about science, teaching and learning science teachers have and what is the relationship they may have with the teachers' science teaching-learning models. The importance of the project has to due with the high spread and impact the YCS program has, this is why it is so important to know to what extent they have influence on the scientific activity's implementation fostered by YCS.

METHODS.

This study is part of a bigger one that follows a multimodal o mixed process (Hernández, 2006), which involves the complement between the application of a dominant qualitative strategy and elements of a specific quantitative design. In this context, the following is done: a) a qualitative approximation to the studied phenomenon, through description, systematization, and analysis of teachers' beliefs, distinctive elements in their practices, experiences and episodes considered significative to their experience in the YCS program, and b) gathering of information using instruments (questionnaries). Sixty one teachers from three different schools, teaching in three municipalities of Valparaíso constitute the sample for the study. The questionnaire is composed by 56 items distributed in four dimensions formulated as statements and organized randomly, in Likert's format, each of them had four possible answers: Completely agree (4), Partially agree (3), Partially disagree (2) and Completely disagree (1). For this publication we present the questionnaire's results, and we are leaving for a subsequent publication the rest of the aspects that have been mentioned in the text. Microsoft Excel 2003 was used for statistical analysis, which had a moderate rationalist epistemological approach.

RESULTS.

In table N° 1, the teacher's preferences respect to the 56 items of the questionnaire are examined, their answers are presented in averages ($\geq 3,0$) and deviation ($\leq 0,9$). Based on the data it can be inferred that for educators, science is an activity socially and historically conditioned, conducted by scientists that have different strategies which cover processes of intelectual creation, empiric validation, and critical selection; with them a temporary, relative and changing knowledge is built. According to this and in congruence with other work (Porlán, 2004) the level of formulation of science image seen fits more alternative approaches. (40 %). The results show three tendencies: a) a traditional model, focused on verbal transmission, b) technological, focused on the objectives as axes of the practice and reference points to evaluate the students' learning, and c) alternative, when the complex character of the student's engagement and the teacher's role needs to be highlighted (46%). The beliefs about science learning from the sample constituted by teachers presented diverse approaches; a set of declarations near to the idea of learning by building of meaning was detected (58%), without absolute and terminal reference points that have to be reached necessarily.

Dimension	Factor	x	σ	*i*	*f%*
Image of Science	Racionalism	3,4	0,6	32/61	27
	Empirism	3,5	0,5	38/61	33
	Alternative	3,7	0,3	46/61	40
Didactic Model	Traditional	3,3	0,7	23/61	20
	Technological	3,6	0,5	40/61	34
	Alternative	3,8	0,3	53/61	46
Theory of Learning	Formal	3,2	0,8	15/61	16
	Construction	3,4	0,6	26/61	58
	Assimilation	3,9	0,1	58/61	26

Table 1: Interpretation of obtained factors (INPECIP).

Finally, Table 2 shows us a summary of the beliefs about concrete conceptual field teaching. Here, a 59% of the teachers presents an hybrid teaching model. In this sense, we assume that the polled ones have a traditional epistemological-dogmatic notion, characterized by a racionalist image of science, with an academic, traditional teaching model that pretends to own the true, definitive and unquestionable meanings and knowledge, and, on the other hand, the existance of constructivist and evolutive rationalities. Nonetheless, we consider there is a lack of evidence to affirm these ideas..

Dimension	Factor	%
Teaching Model	Hybrid	59
	Not determined	41
	Determined	0

Table 2. Interpretation of beliefs about teaching

CONCLUSIONS AND IMPLICATIONS.

From the analysis of the main components of a set of declarations of ITPSB (Inventary of teachers' pedagogical and scientific beliefs, Liker-type questionnaire, IMPECIP for its acronym in Spanish) a series of factors obtained were organized in four hypothetical tendencies. Regarding the image of science, the teachers do not show a clear tendency. An explanation to this might be that they lack of knowledge or constructs about the subject in particular, but that is not necessarily a priority for this level. For beliefs about teaching and evaluation, a more alternative position can be seen; the reason could be a better command of knowledge about the new learning theories that are not specifically related to science. In preliminary results most of the teachers have an hybrid teaching and leaning model, this mixture is directly related to the diversity of epistemological and pedagogical beliefs that each of them has according to their experience, continued training, pre-service training, and finally, a result of this would be their professional practice. These results are the basis for the next work stages, which are linked to the follow-up process during the implementation of the YCS workshops.

INQUIRY-BASED ANALYSIS OF EARLY YEARS CHILDREN BOOKS: DEVELOPING SKILLS FOR LATER SCIENCE EDUCATION

Abstract: Distinguishing fact from fiction is a key feature of science. We investigate the use of children literature to develop this ability among 4-6 year old pupils. To this effect, we chose a children book where special laws, different from real-world natural laws, govern the fiction. Eight teachers were trained to teach a specially designed inquiry based teaching sequence. During the sequence, the children built a real-world device (well and pulley) of which the narration can be considered a literary model. They were then brought to compare the predictions of the model with their observations, and to comment on the contradictions. It appears that children can easily be brought to cross the gap between a literary fiction and a real-world experiment, and to awarely use the results of the latter to confront the predictions of the former.

Keywords: Modelling. Children literature. Experimental verification. IBSE. Impossibility.

INTRODUCTION

While inquiry-based science education has been since 2002 the recommended method in France for introducing very young children to science, it seldom gets beyond "discovery of the world" practices. Classical activities at the kindergarten level (*école maternelle*) are discovery of the five senses, plantation of seeds, actions on materials (making apple juice, dissolution…) (M.E.N., 2005; B.O.E.N., 2008). Such activities are usually intended to give the children a first impression of basic scientific methodology, mostly by insisting whenever practicable to implement the sequence: Proposition of an idea / Test / Conclusion (Coquidé & Giordan, 1997; N.R.C., 2005).

Yet, very young children can be also introduced to other skills involved in science education. We will focus here on those called on by the utilisation of models — namely, the skill to navigate between the real world and a model in order to test the predictions of the latter.

DISTINGUISHING FACT FROM FICTION

This skill is a key feature of science. Nevertheless, whereas the distinction between fiction (usually simplified models) and reality is obvious enough to remain mostly implicit among scientists, it constitutes a challenge for children. Before it becomes a pattern of thought, it has to be internalized, thus calling for explicit teaching (Etkina & al., 2010; Tiberghien, 2009).

While formal models, often involving mathematical representations, are commonplace in professional science as well as, to a certain extend, in high school, they are obviously irrelevant as far as very young children are concerned. To a lesser extend, the same can be said of analogical models (e.g. a polystyrene ball representing the Earth). Stories being a major tool in kindergarten, literary models, seldom used in more advanced scientific contexts, are in fact likely to constitute the first contact of young children with the concept of modelling.

Biology is a favourite subject (Lamap, 2006), but some stories can also be used to work on elementary physics. Even very young children can detect their most blatant imaginary aspects: real-world animals don’t talk and don’t wear clothes etc. Literary fictions are identified as special worlds; they can nevertheless be used to generate questions pertaining to science since “the fiction’s dominant, albeit unsaid, reference is the real world governed by natural laws” (Bruguière & al., 2007).

But can very young children also acknowledge the fact that special laws, different from real-world natural laws, may govern a given fiction? How do they react to such a dissonance? Do they show ability to switch explicitly from one world to the other?

METHODOLOGY

In order to investigate these abilities among 4-6 year old children, we have developed a complete inquiry based sequence around one of the most popular children books in French kindergarten, namely *Plouf !* by Philippe Corentin (Corentin, 2003; Blanquet, 2010; Soudani & al. 2011). Besides the usual literary conventions of such fantasy (talking animals, etc.), the storyline involves an internal contradiction if the diegetic “physics” is to be considered equivalent to real-world physics. During the sequence, the children elaborate a real-world experiment of which the narration can be considered a literary model (Blanquet & Picholle, 2011). They are then brought to compare predictions of the model with observations of a controlled experiment, and to comment on the contradictions.

Eight teachers were specifically prepared to teach this sequence. In France, kindergarten pupils usually work in small groups (4-6 children), the teacher dealing in turn with each group while the others work autonomously. Two devices were used in order to evaluate the appropriation of the sequence by the children. On the first hand, four teachers were involved with their classes in a festive science event (Blanquet, 2009); ten teams of three pupils were directly observed while hosting for other pupils a workshop based on a simpler — but still inquiry based — version of the sequence they had beforehand discovered in the classroom. On the other hand, one senior teacher and three teachers in training and their pupils have been audio- and video-taped (Visa, 2008) while making their way into the sequence. The exchanges between the teacher and small groups were then transcribed and analyzed and the children were later interviewed by pairs.

MAINLINE OF THE *PLOUF !* TEACHING SEQUENCE

The story revolves around a well and a pulley. A hungry wolf falls into a well, thinking there is cheese at the bottom; using a pulley, a pig helps him out, while descending himself down the well; then, a family of rabbits helps the pig out by the same device; ultimately, the wolf helps the rabbits out and gets himself down the well again, still using the pulley. After reading the story, the teacher verifies the good understanding of its different steps through questions and small-groups activities.

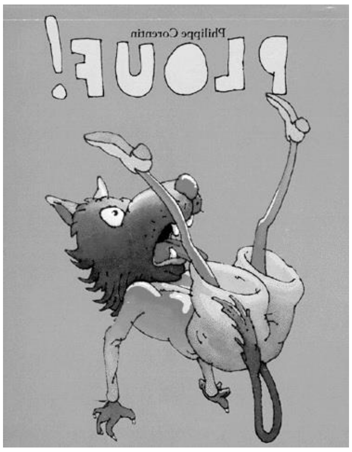

Fig.1: *Plouf!*

Fig.2: *Plouf!* well and pulley device

The sequence then brings children to conceive and build a real-world well-and-pulley device. First, the teacher proposes activities to help pupils to establish the analogy between the book's device and the ones they are going to build. Once it is operational, they are asked to reproduce the different steps of the story, using bottles of various weights with glued images of the imaginary animals on it (Fig. 3). The last step of the story proves impossible to reproduce, since the previous ones imply that the wolf-bottle is lighter than the "rabbits" one [1].

Exchanges among children and with the teacher yield an emphasis on the difference between what happens in the story and with the real-world device. The contradiction is then discussed in the group of children and with the teacher. The children's propositions around it (changing the weight of animals etc.) are implemented. The sequence is eventually re-done and different kind of well-and-pulley devices proposed, with a back and forth alternation between the story and the real-world devices, between prediction of behaviours and their experimental verification.

Fig. 3: Real-world well-and-pulley device

Fig.4: 5 years old hosting a science event: *You try it!*

APPROPRIATION OF THE TWO-WORLD CONCEPT

While (thoroughly enjoyed) repeated readings and real-world experiments were usually needed in the classroom to bring the children to notice the different behaviours of the fictional and real-world devices, they did not appear to be confused by different laws being involved in the two distinct worlds once these difference had been acknowledged. Although specific to this special story (as opposed to classical fantasy conventions), the fictional laws governing well-and-pulley devices in *Plouf!* were accepted as "non-real", apparently without any loss of pleasure in subsequent readings, much to the contrary.

The guidance from the teacher during these inquiry-based learning sequences made it difficult to decide whether the children did, or not, understand the relationship between the two worlds, and the interest of navigating between them. It appeared more clearly during the interviews and the scientific manifestation, free from adult interference. Children were using in context the same kind of questions to their young visitors that the teacher had done previously with them. Typically, after their rendition of the story, they were eager to ask "Can you do as in the story?" (*Est-ce que tu peux faire comme dans l'histoire?*) Furthermore, we observed regulation of the sequence by other children-hosts, on the abstract level. As a host would try and omit the question, another would stop him, insisting that "First, you must ask if he can do as in the story" before explaining "what is the well and what is the pulley" (*il faut d'abord lui montrer ce qui est comme le puits et ce qui est la poulie*) before "doing things" and, then only, acknowledging the impossibility of the last step. The exchanges between hosts clearly established their ability to navigate between the real world and a model, and the understanding of its basic utility. (It nevertheless seems dubious that this achievement was transmitted to their young visitors. The basic educational goal of the event was reached just the same, since all children thoroughly enjoyed themselves while "doing science").

CONCLUSION

It thus appears that 4-6 y.o. children can easily be brought to cross the gap between a literary fiction and a real-world experiment, and to awarely use the results of the latter to confront the predictions of the former. The nature of this skill is essentially the same that they will later need to confront analogical or mathematical models to scientific experiments. Further studies would be needed to establish whether of not the acquisition and consolidation of this skill in early year science education might improve later performance in learning science.

NOTE

1. It should be noted that, while many sequences using this album with young children are available on the French Internet, hardly any of them makes any mention of this impossibility. Do teachers notice it? The question remains open, but the author of the book received only a couple of letters addressing the problem, among hundreds over two decades (Corentin, 2011). Teachers don't usually question the physics of a story.

FICTIONAL STORYBOOK AS A SCIENTIFIC AND EPISTEMOLOGICAL QUESTION-BUILDING TOOL FOR PRIMARY SCHOOL

Catherine Bruguière[1], *Eric Triquet*[2], *Mohamed Soudani*[3] *and Jean-loup Héraud*[4]
[1234] S2HEP, EA 4148, Université de Lyon, Lyon F-69000, Université Lyon 1, Villeurbanne, F-69622, France

Abstract: This work is focused on a specific type of children's storybook literature, specifically realistic works of fiction, in which the plot reflects laws of nature. This paper explores two storybooks : *Fish is fish* by L. Lionni and *The Promise* by J. Willis et T. Ross. These two stories express implicitly notions of biological development. An analysis of the fiction and the non-ficiton, which exists in these storybooks, allows us to explore how the story's intrigue as well as certain problematic wording can constitute a starting point for scientific as well as epistemological research on the development of living things.

Keywords: Fictional storybook, possible world, problematic process, biological phenomena

INTRODUCTION

The direction taken by the French curricula for Elementary Schools in recent years (2008), which now prioritize 'speaking, reading and writing' across the disciplines, has opened up new opportunities for science-teaching at this level. While this orientation has led to an increased number of readings of informational books, it is less common to use fictional storybooks.
In a previous publication (Bruguière and all, 2007) we showed the potential effects on pupils learning of storybooks, leading to an interrogation of a scientific and epistemological nature. Here, we will focus this reflection on the functioning to the relationship between real and possible worlds in two unusual fictional storybooks: *fish is fish*, (Lionni, 1970 translated in French 1981) and *the tadpole promise (*Willis and Ross, translated in French 2005) in which the plot is based on the different physical changes which each character experiences. The aim of our research is to identify the role of fictional storybooks in scientific and epistemological question-building. The view of science taken in this study is one that emphasizes an investigative nature and the desire to broadly view the contexts for investigation, as noted by the Yager's definition, cited by Butzow (1998) : "*Anything that promote explanations, encourages the creation of explanations, or calls for verification and validation is scien*ce". Furthermore we see with Canguilhem, (1965) that « *Knowing is not so much about knocking up against reality as validating a possibility by making it necessary. In this case, the origins of a possibility are as important as the demonstration of a necessity*. »

BACKGROUND

In reference to possible worlds semantics of Hintikka (1989) considers that there is no break between the possible and real, we are in a more epistemological proximity between science and the story in a report of opposition. For Hintikka, the fiction of possible worlds built on the basis of a real world or a possible world which may or may not occur and towards which we can distinguish between two epistemic attitudes: one on the mode of belief or another mode of knowledge. If knowledge is true by definition relates only to the real world, the belief can be true or false but Hintikka false belief is not at all a negative because it opens the possibility of coming true in a world alternative. We can appreciate the scope of the heuristic fiction by creating all possible worlds helps to get students of the register of belief in the register of knowledge, and develop in them a critical epistemic attitude, which is the issue of the science education. The posture of Hintikka cannot be described as Bachelard in the sense that there is no rupture between common knowledge and rational knowledge. In the same way Bruner (2002) thinks, "When we invent possible worlds of fiction, we can never really leave the world which we are familiar." Bruner (2002) postulates an effect of fiction on the construction of a rational relation to reality. This epistemological position opposed to that of Popper (1985) for whom the stories are fiction out of science, do not belong to the same world.

Children 's literature may be playing an increased role in science classrooms. Nevertheless, most studies have found many inaccuracies in science trade book and have highlighted the need for teachers to carefully select appropriate trade books for classroom use (Rice 2002). To assist in this process, several checklists of books included the identification of inaccuracies have been created (Rice, 2002). For example, Schussler (2008) critically analyses numerous science trade books and asses the information they contain about plant reproduction. In theses studies the sample of children's books include fictional storybooks, narrative and non-narrative informational texts. However, the fictional storybooks aren't in keeping with the same plane in relation to scientific validity. In the fictional story, we cannot consider elements like false but like plausible or possible. The interest of our study lies in focusing on the fictional storybooks for there has not been much research in this field. In this way, Butzow (1998) estimate that fictional storybooks can be used to keep alive this sense of wonder and can become a vehicle through which science is learned. As Bruner (1996) or Ogborn and Millar (1998) said about a similarity between narrative and scientific explanation, we make the hypothesis that the plot structuring for the story is also structuring to generate scientific and epistemological questions. In the context of didactic studies (Butzow and all, 1998) which takes the articulation between reading and writing as a necessary condition for the process of conceptualisation, we hypothesize that the use of fiction will improve the comprehension of the real for primary-school children. Thus, the illustrations and texts cannot be interpreted without interrogating the real objects to which they refer but from which they are differentiated in perceptive and conceptual terms. We will see how this narration is not a mere fictional story having no relationship to the realities of animal life, but instead uses animals so to impart knowledge to the reader about how animals truly live, act and behave in nature. This provokes the reader to reexamine his previous understanding of nature, while at the same time encourages him to develop his knowledge even further.

RESEARCH QUESTION AND HYPOTHESIS

In this background, we think that fictional storybooks present a learning opportunity that cannot be obtained through the use of traditional textbooks. Fictional storybooks create many possible worlds that are not completely unrealistic and have links to the real world.

Our global aim is to identify the role of fictional storybooks in scientific and epistemological question-building. More precisely we propose to study in our communication one of the narrative functions , the role of fictional narrative in the problematic process.

The problematic process will be explored according to two levels : a global level, around the structure of the plot and a more local level, around specific wording. Indeed the story books presents a « golden sentence » at the heart of the intrigue (Tompkins, 2003) which represents the message of the storybook. The repetition of this wording throughout the course of the story takes on multiple meanings in a storybook that can be problematic.

In this way we consider two hypothesis in the problematic process :

- The plot structuring for the story is also structuring to generate problematic questions.

In others words, the story presents a fictional problem, which corresponds to a scientific problem.

- The diffents meanings taken by a wording (title or term) throughout the story generate problematic questions

METHOD

Our case study compares two fictional storybooks: « Fish is Fish » (Lionni, 1970 translated to French in 1981) and « The Tadpole Promise » (Willis and Ross, 2003 translated to French in 2005). These books were selected for the three following didactic reasons:

- They have yet been chosen by science education researchers as examples that promote an integrated approach (Butsow, 1998, Avel and Lanoizelé, 2008);
- They offer a story related to science, but this story is not expressed in scientific terminology. The narrative glues together the fiction and the real world and presents them at a level of accessibility that is appropriate for the child;
- Their plot is based on biological phenomena, in other words, on the different physical changes which each character experiences. More, the plot is based on the same disruptive event, the same incident : the occurrence of hind footed to the tadpole.

For this study, we will examine on one hand the development of the plot, from its beginning to its outcome. Using the Larivaille Method (1974) we will look at the five following steps : Beginning state- Intrigue- Development – Resolution- Final state. According to this method, the plot is defined as a transformation from a balanced state (Beginning state) to another balanced state (Final state). The goal of the analysis is identified as how the biological phenomena connect to the different steps of the plot in the two stories.
On the other hand, we will examine the differents meanings taken on by problematic sentences throughout the story. How do the meanings evolve ? What new scientific questions will these new meanings provoke ?

RESULTS

Results 1 : The plot generate analytical and problem-solving tools

We will see how to fully understand the plot one must fully understand the scientific phenomena because the development of the plot in the two stories is overlapped with the biological phenomena (tableau 1).
The plot revolves around the relationship that unites two characters. In The tadpole's promise, the relationship is romantic, while in Fish is Fish, the relationship is between friends. In the two stories, the plot is based on the same disruptive event : the appearance of hindlegs on the tadpole which has the potential to threaten the relationship between the two characters. Is it possible for the relationship (love or friendship) between the two characters to continue despite the morphological and anatomical changes which effect the tadpole ?

The plot	***Fish is fish***	***Tadpole's promise***

<table>
<tr><td>Beginning state</td><td colspan="3">In two different environments, at the frontier between the pond and the bank of the pond (in Tadpole's promise: Where the willow meets the water a tadpole met a caterpillar.)
The opening places the development of the characters at the same time: when they are larva.</td></tr>
<tr><td rowspan="2">Intrigue development</td><td>First complication</td><td>Fact : The appearence of hindlegs on the tadpole distinguishes the tadpole from the fish, making them different.

Scientific problem: Is the appearence of hindlegs a clue that the tadpole does not belong to the same species of fish as the minnow ?
What can allow us to say that the tadpole is a fish or a frog?</td><td>Fact: The appearance of the two hindlegs on the tadpole changes the tadpole.

Scientific problem: Does the appearance of hindlegs change the identity of the tadpole?
Do these morphological changes exist for every animal?

→ The first complication happens three times: he grew legs, then he grew arms and finally he has no tail.</td></tr>
<tr><td>Second complication</td><td>When the tadpole develops into an adult frog and jumps out of the water onto the bank. The frog discovers the terrestrial world.

When the frog comes back, he describes to the fish the extraordinary things that he has seen: a bird, a cow and so on. The fish imagines the different animals.

Scientific problem: how can we imagine animals that we have never seen before? Animals</td><td>When the caterpillar develops into a butterfly but can't recognise the tadpole who has developed into a frog.

Scientific problem : does the same animal persist between the larva and the adult form?</td></tr>
</table>

		that don't live in our environment?	
Resolution		When the '*fish jumped clear out of the water onto the bank, … he lay gasping for air, unable to breathe or to move'. 'Luckily, .. the frog.. pushed him back into the pond'.* **Scientific problem**: Why can the frog breathe on the bank and not the fish, while the tadpole can breathe in the pond like the fish?	In *Tadpole's promise*, the resolution of the story happens when *the frog leapt up and swallowed her.* **Scientific problem** : Why can't the tadpole eat the caterpillar while the frog can eat the butterfly?
Final state		When the frog and the minnow remain friends. Each one stays in his environment. **Scientific problem** : what biological relationship exists between an animal and its environment?	The frog is alone, the butterfly has disappeared. *The frog waits thinking fondly of his beautiful rainbow wondering where she went.* **Scientific problem** : What becomes of the butterfly when she has been eaten by the frog? Is she still 'butterfly matter' or has she become 'frog mater'?

Tableau 1 : The events of the plot with the biological phenomena overlapped

Thus, in the two stories, biological phenomena are overlapped with the events of the plot. They are connected to each step of the plot and the plot is resolved according to real world restrictions.

Results 2 : certain wording generates problematic questions

Here the analysis consists of capturing the problematic dimensions of the storybook, which can often be found in either the title or the content of the story. In *Fish is Fish*, the problematic dimension is highlighted in the title. It is interesting to note that the French translation, *Un poisson est un poisson*, differs from the original English in the sense that the indefinite article, *un* , is used. This makes it clear that any fish, such as cod, trout, brill, bass, etc. can be part of the same specises. In *Tadpole's promise* the sentence *Promise you'll never change,* is repeated throughout the story and carries with it this problematic character. The promise is problematic because it is something that can never be realized. A tadpole will inevitably change into a frog.

Here we propose to focus on the different ways to read, question and understand the problematic wording : In *Fish is fish*, the changes in meaning occur while reading the storybook happens at two precise moments in the story.

1/ During the first complication

« One morning the tadpole discovered that during the night he has grown two little legs. "Look" he said triumphantly. "Look, I am a frog !" "Nonsense", said the minnow. "How could yo be a frog if only last night you were a little fish like me ! They argued and argued until finally the tadpole said, "Frogs are frogs and fish are fish and that's that !"

We can consider that the incomprehension between the two characters comes from different meanings seen in *Fish is Fish*. The two characters express implicitly ou explicitly two opposite meanings
For the fish: *Fish is fish* means implicitly that a fish stays a fish. The fish is considered as a single fish. Consequently the tadpole who is his inseparable friend and thus lookes like a fish will stay a fish. In fact, both characters are wearing the same green and red colors. Their expressions are similar, the graphics of the eye and mouth opening, give them a little « air de famille ».
For the tadpole : Fish is fish means explictly that a single fish is one member of the fish species.
If the fish gives the same meaning to the two fish terms, the tadpole gives a different meaning to each fish term, an expression that he applies to frogs and that he could apply to every specises.

The conflict of meaning permet de relier la question de l'identité à celle du développement. Plus encoe, The link between 'tadpole' and 'frog' (qu'exprime en parlant de grenouille et non plus de têtard) introduces the idea of the permanence of the identity of the animal during its development

Fish is fish, here is set against the truth spoken by the tadpole, who comprehends Fish is fish only from the point of view of frogs as a group
The use of the plural of 'grenouile' / 'frog' highlights the fact that the French 'un' (absence of pronoun in english) of the title refers to a plural.
The link between 'tadpole' and 'frog' introduces the idea of the permanence of the identity of the animal during its development

2/ During the resolution

The crucial experience of the fish allows the fish to test his beliefs about his identity. He could not breath on land like the frog, therefore he is not a frog but a fish. In this situation, the breathing becomes as a relevant criteria to define identity. The appearance of the hindlegs did not act as a criteria of distinction for the fish.
This time the fish gives explicitly with "you know, you were right, fish is fish" the same meaning as the frog does. We go from the truth about a single character (tadpole/frog) to a state of shared knowledge after an experience which almost cost the fish his life. *Fish is fish* is no longer only the truth about one character, but words proven by experience
This work opens up a reflection of the criteria of animal classification

CONCLUSION AND IMPLICATIONS

We propose to consider a new kind of picture book define as « realistic fiction », meaning that the narrative may convey certain elements of scientific knowledge
More precisely, these specific fictional storybook can be characterized as «realistic fiction» if :
- the story presents a fictional problem, which corresponds to a scientific problem,
- the fictional narrative is held together by scientific phenomena. The plots question the real world.
- there is a problematic wording

Thus, to fully understand the «realistic fiction», pupils must fully understand the scientific phenomena. In this way, such story book question beliefs ans interrogate our representations of the world allows one to explore the possible explanation by confronting fictional imagined worlds with the real world, allows one to connect the bordaries of the real world through the use of the imagined possible worlds which are created by fiction.
As Butzow (1998) said, in these books, we think that the scientific content is not merely a chance to introduce a reading, it becomes a « character » in the story, without which the book would cease to exist. The «realistic fiction» is not considered a pretext for introducing scientific content. Rather, it creates the context for the scientific problem. The both characteristics: multimodal aspects of texts and the association to the strong science theme related to the plot, open new perspectives for literacy learning. Such picture books represent an under- explored resource for teaching science at the primary school level. Our research perspective is to explore how these storybooks can be effectively used in the science classroom.

TEACHING ANIMAL CATEGORIZATION IN PRESCHOOLERS USING TYPICAL - NON TYPICAL EDUCATIONAL ENVIROMENTS *

Eirini Gkouskou [1] & Dimitris Koliopoulos [2]
[1] Preschool teacher, PhD Candidate, Department of Educational Sciences and Early Childhood Education, University of Patras, gouskou@upatras.gr
[2] Associate Professor, Department of Educational Sciences and Early Childhood Education, University of Patras, dkoliop@upatras.gr

Abstract: The aim of this research study is to present the goals, the content and some evaluation elements of a teaching intervention for preschool children concerning animal categorization. The intervention combines typical and non typical educational characteristics and takes place both in the school class and in a zoological museum. More specifically, we will present the cognitive objectives of the intervention which are the following: (a) the familiarization of children with various samples of animals, (b) the movement of children's ideas from using anthropomorphic or functional criteria to the use of morphological criteria for classification of animal samples, (c) the identification of new samples of animals with one of the constructed categories of animals and (d) the creation of a new class of animals in case of the animal sample does not fit in any of the constructed categories. In this study we will focus on the characteristics of teaching activities which take place during the visit to the zoological museum at the University of Patras. Some preliminary results which support the hypothesis that the museum educational activities have a positive impact on the fulfillment of the mentioned didactical objectives will be presented.

Keywords: Preschool education, zoological museum, animal classification, cognitive precursor models

INTRODUCTION

The present study is part of a wider research related to the design and evaluation of a teaching intervention which addresses to preschool children with the cooperation of school and zoological museum. The educational program is one of the forms of active involvement in school activities on science and technology (Koliopoulos, 2009), which promotes a structured scientific knowledge (Martin, 2004; Piqueras et al. 2008) and is regarded as a rich educational activity, which contributes to the achievements of scientific literacy (NRC, 1996). The latter form is usually based to the cooperation of the museum with the school, which, as noted, can combine the advantages of the museum and the school environment in order to achieve its full educational goals for visitors - students (Anderson et al., 2010). Studies have shown that students who have worked on subject before visiting a museum foundation and are prepared for the visit learn more from their experience (Griffin, 1994).

The objective of the teaching intervention is to be constructed by children a precursor model of classification of animals. Children learn about animals in a variety of ways. In zoos and museums, which children have been visiting ever since these establishments opened their doors to the public (Tunnicliffe & Reiss, 2000). The zoological museum of first generation is the oldest and most conventional type of museum where there are exposed collections of animals usually embalmed. This type of museum seems to be a suitable environment because of an explicit or an implicit way, it gives meaning to its collections through the concept of systematic classification of animals.

In parallel is has also been noted that children of this age can build precursor models of natural sciences through a socio-cognitive teaching approach according to which they are able to form explanatory forms compatible with both the knowledge of science and their own mechanisms for recruiting and processing knowledge (Ravanis, 1996). In this study will be present the goals, the content and some evaluation elements of a teaching intervention for preschool children concerning animal categorization.

THE DESIGN OF TEACHING INTERVATION

The principles of the design of the proposed teaching intervention are referring to (a) the structure and content of school knowledge on the subject, (b) the constructive approach of teaching and learning of science in early childhood education and (c) the museological conception on the teaching effectiveness of programs when they are carried out with the cooperation of school and museum environment.

The cognitive field which is the subject of teaching and learning in our case is the field, of the classification of animals. There are different theoretical starting points within which the concept of classification takes a different meaning. The currently accepted theory of evolution has led to the grouping of animals according to their relationships or the affinity of species (phylogenetic approach) and their common origin (genealogical approach). According to this theory the animal species are transformed and evolving entities and the hierarchical clustering result from a careful examination of similarities and differences in order to distinguish between the features which are due to their common origin and not the analog characteristics which are due to similarity in their function (Mayr, 1982; Lecointre, 2007). Is it possible through that, this epistemologically valid knowledge can be the scientific knowledge of reference for the teaching of the subject in preschool education? Our interest focuses of course on micro-classification, a field that is examining the methods and principles with which are identified and described the types of organisms (Mayr, 1982).

It is considered that in our approach it is impossible to introduce the types of living beings (here animals) as a biological species (taxa) in the modern sense of the term. In contrast, we use the concept of typological kind, which it may derive from theoretical framework where the notion of classification is recognized and becomes accepted without resorting to the theory of evolution, but it does not contrast with the concept of biological species). The typological (or morphological) type is considered to be a separate and stable entity, where the species are determined by fixed, key characteristics, usually morphologically. Scientists officially recognized a kind by defining a sample type that was recorded and deposited to a museum in order to represent the ideal form or morphology of the species' (Hickman, Roberts & Larson, 2001). Even today there are scientists who study only preserved specimens-types for which the dominant conception of species remain typological (Mayr, 1982; Hickman, Roberts & Larson, 2001). It is considered that this choice doesn't represent, at first an epistemological rupture between children's conceptions (who use mainly anthropomorphic or functional criteria to classify animals) and the knowledge where the criteria for classification of animals are purely morphological. It is also assumed, that the transition from the empirical criteria to criteria concerning the theory of evolution would be difficult or impossible because of the enormous distance between the two cognitive structures. So, the conceptual component of the proposed school knowledge is established, firstly as a didactic transformation of knowledge of the typological species and secondly, as a simplification of the collections of the Museum of Zoology of the University of Patras used as a museum reference. There are created, simple collections (Lecointre et al, 2007) and were formed four typological species, reptiles, birds, fish and mammals. As main morphological features of distinction between typological species were considered the anatomical characteristics and the nature of the skin (scales for reptiles, feathers for birds, scales for fish and hair for mammals). Yet they were established collections of samples of animals which form the phenomenological basis of intervention.

As for the methodological dimension of the proposed school knowledge, the emphasis was on the process of systematic observation of animals which responds to specific questions, is used to confirm some assumptions and is based on finding criteria of similarity or comparison (Guichard, 1998; Lecointre et al , 2007).

The constructive approach of teaching and learning of science in early childhood education is the second principle we take under consideration. This approach is based on assumptions according to which preschoolers can build conceptual models of precursor science (Zogza & Papamichael, 2001; Ravanis, 1996). It has been noted that the construction of these models can be possible within the interventions of teaching where the teaching objectives have been based on the cognitive obstacles or the general cognitive abilities of children of this age (Ravanis, 1996, 2005). Thus the teaching activities are designed so as to be used constructively the cognitive capabilities or/and removing the cognitive obstacles that children have (Ravanis, Koliopoulos & Boilevin, 2007; Koliopoulos & Argyropoulou, 2011). As for the construction of the concept of classification by preschool children, researchers note that children of this age use basically the anthropomorphic and the functional criteria (eg, habitat and movement) rather than morphological criteria to classify the different types of animals (Trowbrigde & Mintzes, 1988; Kattmann, 1998; Zogza & Papamichael, 2001). The proposed teaching intervention, therefore, emphasized on activities that aim at (a) the ability of the children to distinguish and name samples types of animals and (b) at shifting children's interest to the morphological characteristics of the sample-types through an organized and systematic observation of images and zoological exhibits. Examples of such activities are provided in the following section.

Finally, as for the educational environment in which will be implement the teaching intervention, was chosen to approximate three phases, each of which implemented in a formal (school) or non formal (museum) learning environment (Table 1).

Table 1 here

Each of the three instructional phases corresponds to qualitatively different educational activities (Allard, Boucher & Forest, 1994; Paquin, 1998). In the preparation phase before the visit, which takes place in school, questions are submitted and a discussion is developed concerning the museum object. On the phase during the visit which takes place in the museum, is carried out the data collection and analysis as well as the systematic observation of the museum object. Finally, in the phase after the visit which takes place in school, the aim is the further processing of data obtained in the previous phase, the drawing of conclusions and the evaluation of the constructed knowledge. This approach is based on an inquiry-based teaching and learning method engaging students in identifying relevant evidence and reflecting on its interpretations (http://fibonacci-project.eu/).

THE CONTENT OF TEACHING INTERVENTION

The cognitive objectives of teaching intervention which correspond to the desired cognitive progress of children are the following: (a) the familiarization of children with various samples of animals, (b) the movement of children’s ideas from using anthropomorphic or functional criteria to the use of morphological criteria for classification of animal samples, (c) the identification of new samples of animals with one of the constructed categories of animals and (d) the creation of a new class of animals in case of the animal sample does not fit in any of the constructed categories. Then we describe the key features of teaching activities which we assume that will contribute to the achievement of these objectives.

Activities prior to the visit

The activities carried out before the visit included activities where according to the principles of constructivist approach are investigated primarily the initial conceptions of children on the subject of teaching intervention. Within these activities the children are asked to recognize and name the samples of animals which are depicted in a series of cards which constitute the first simple collection of animals. In addition, children are asked to create groups of animals by classifying the various samples of animals which are depicted on the cards and indicate the criteria used. Finally, there are activities aimed at developing children's interest on their visit to a museum of Zoology.

Activities during the visit

These activities are carried out during the visit to the Museum of Zoology of the University of Patras. This particular museum exhibits mainly taxidermies animals placed in showcases that correspond to categories of animals, perfectly compatible with the typological categories of items that we seek to be constructed by children. There were introduced activities where children, through systematic observations, were asked to deconstruct the categories of animals that have been created in school and to compare their own categories with the categories adopted by the museum. Finally, children are asked to reconstitute the animal categories based on their observations and the emergence of common morphological features for each category. An example of an educational activity that took place in this phase is represented in Table 2.

Table 2 here

Activities after the visit

During the activities after the visit, experiences of the visit are invested in the construction of new knowledge from the children and the achievement of learning objectives of the program is assessed. More specifically, children were asked to compare the groups of animals which themselves had built at the beginning of teaching intervention to those created in the museum. They were also asked to include new images of samples of animals to the categories of reptiles, birds and fish, that were already familiar to them, or to suggest a new category (mammals) in case of the appearance of a new morphological feature.

THE COGNITIVE PROGRESS OF CHILDREN

The results of the analysis of perceptions of children's categorizations of animals came mainly from the *Pre – Post test (interview*), which took place before the beginning and after the completion of the educational program. We use individual semi structured interviews for all the children who participated in this pilot study- educational program. Complementary, the second unit of the results consists of the data which collected through observation of the subjects of the research, during the visit to the zoological museum.

The main conclusions which drawn after the final interview are as follows: Three of the nine children considered to have built a vision classification of animals based on purely morphological criteria, because they were able to identify, name and classify all samples of animals were given, while to suggest a new class of animals other than those which studied the museum and to justify their presence by using morphological data. Five of the nine children are in the process of building a culture of classification of animals based on morphological criteria .These children fail to nominate at least two categories of animals, but not always using purely morphological criteria (introduced, for example, the criterion of residence). They also recognize a new category of animals without name it. Finally, only one out of nine children who participate in this pilot study seems not to cognitive progress notes remaining on his original ideas.

Some complementary data which obtained during the children's visit the at the museum are indications that the activities of target observation suggested to the children contributed to the final construction of the classification of animals by using morphological criteria. Here are some examples of children's conversations with the researchers during the activity identification of exhibits on display in the zoological museum: "... This is a big peacock ... I have not seen it before" (Spiros). "... Look like a fish ... we see those in the sea during the summer , but here these look bigger " (Androniki). "... all snakes are here ..." (Themis). Infants also through the educational activity which took place during the visit to the museum identified the representative characteristics of each group (birds, reptiles and fish). "Here is the group of birds all have wings ... are all around, in the nearby showcases .... and small and large“ (Francesca).

The next educational activity which took place during the visit to the museum, where the children have to compare samples of animals depicted in these photos of exhibits and trying to assign each exhibit with the photograph, appears to be a suitable environment to move children from the original 'experiential' criteria for the classification of animals on criteria which mobilize mental representations based on the morphology of animals.
Characteristic is the phrase that Ianthi looking at an exhibit in a showcase says: "... This little bird is the same as what we saw in the photo at school ...and in this one ... has many ... colors in the wings ... and small legs as the other.:"[meaning the exhibit depicting in the photograph], (Ianthi). While Phoebus indicate "... but since that is not the same [pointing to the pairing just made his classmate between photography and the exhibit], a different color in the wings ... we decided to find the same ... this is the same“, (Fivos).

CONCLUSIONS

A key finding of the research activity developed during the planning of this educational program described here is that the collections of the Zoology Museum of the Univesity of Patras can be attributed by meaning, which can be potentially appropriate educational materials that will contribute to the cognitive and emotional progress of children of preschool education. Theses meanings come from both the nature and characteristics of the museum and, mainly, the objectives and content of each educational program. This means that the museums are possible through the model of educational program to upgrade the communications and educational role while simultaneously achieving objectives of the formal education.
The results of the program, in particular the activities undertaken during the visit, using the empirical basis of the museum (the zoology museum's exhibits) may provide an appropriate environment for children of preschool education to create a variety of meanings, to certain networks operating, rules and standards of interpretation, according to which they will 'translated' their experiences and assimilate the information from these intakes (Ravanis, 2005). So, if some of these networks of meanings, as in the case of the proposed program appears to be set up exactly due to the systematic interconnection of the contents of formal (school activities) and informal (museum activities) form of education, then demonstrate the functional re-

lationship between the two forms of education and this is a central hypothesis in our ongoing investigation.
The positive response of the overwhelming majority of children who participated in this program was another finding of this investigation. But this is not an unusual finding itself as the natural history museum with collections of "teaching remains an advantage that will make [visitors] to admire, be surprised and wonder (Van Praet, 1989). The important questions whether this response is and how the cognitive function in a privileged way is introduced in the proposed model of integrated curriculum. This is another interesting idea to be transformed as a research case study and in the future to be further explored.

LEARNING SCIENCE IN SMALL GROUPS: THE ROLE OF AGE AND INTERACTIONS

Kallery Maria[1]
[1]Aristotle University of Thessaloniki, Greece

Abstract: In the present work we study young children's learning in science in mixed-age small groups. Specifically, we study the performance in science of the younger students participating in these groups, as well as the development of their communication-collaboration skill in an effort to diagnose if these factors are influenced by the number of the older students participating in the groups of a class. Four schools with classes of students aged 4-6 participated in the study. Students were involved in activities with topics from physics and astronomy. Two sources of data were used: Teachers' classroom recordings and children's individual assessments. Results indicate that there is a linear relationship between the performance of the younger children and the number of the older ones that participated in the groups of each of the classes. Similar results were recorded for the communication- collaboration skill. The graphical representation of the younger children's performance in science versus the number of the older children participating in the small groups allows us to predict the expected performance of the younger children of a class depending on the age composition of the groups. The latter can be utilized in deciding the age composition of the small groups in a class with the aim to facilitate the younger children's learning as well as their social interactions.

Keywords: Small-group-learning, Science learning, Preschool science, Mixed-age groups, Social interactions

BACKGROUND AND PURPOSE

Students' learning by interacting with each other than only with their teacher is of much interest to educational researchers and practitioners; it is also a highly evaluated goal (Webb, 1989). To achieve this goal students need a learning environment that promotes the interactive processes of learning which they are preferably exposed to from the lower grades of education (Huber & Huber, 2007). At the heart of this view of learning is the situation or the context within which learning takes place. Taking into consideration that learning is a transactive phenomenon existing in situations created by the teacher for students to learn, and that social interactions and skills allow the individuals to benefit from the opportunities to learn from each other, the teacher can create environments in which students can collaborate with peers and adults. Examples of such are the small mixed-ability cooperative groups the use of which is supported by extensive evidence produced by numerous studies. Small cooperative groups are used in several countries across all levels of education not only for supporting and improving students' learning, motivation and attitudes, but also as a method for handling classes with a large number of students. While small-group-learning has a long history, only in the last decades have researchers studied the interactions among students that facilitate learning, and the factors that lead to different patterns of interactions. One of the factors is the number of the members who participate in a small group. Huber and Huber (2007) suggest that groups should comprise as many members as are still able to interact directly with each other. Another factor that has proved to be important is the age of the members of a small group. Furman and colleagues (1979) maintain that socialization in mixed-age groups serves children in many ways that same-age socialization does not and note that in mixed-age groups, accommodations are required between individuals whose developmental level differs. The following findings are also of importance: a) Children prefer to be taught by children older than themselves (Allan and Feldman, 1976), b) Older children are more effective models than younger children (Peifer, 1971) and c) Reciprocal imitation is more characteristic of children's interactions with older children than with younger children (Thelen & Kirkland, 1976).

Given the above, in the present work we study learning in small mixed-age groups. More specifically, we study the performance in science of the younger children participating in these groups, as well as the development of their communication-collaboration skill in an effort to diagnose if these factors are influenced by the number of the older children participating in the groups. The questions leading our research are:

- How do the cognitive achievements in science of the younger children of a class the students of which work in small groups change in relation to the number of the older children participating in the groups of this class?
- How does the communication-collaboration skill of these children develop over the period of their involvement in science activities?

DESIGN AND CONTEXT OF THE STUDY

The present study, which was conducted in Greece, was designed to be carried out in real classroom settings. Given that in the Greek educational system the only level in which classes are mostly multiage is the pre-primary, the present study was carried out in classes of children aged 4 to 6. In this level, ages are grouped as follows: 4-5 pre-kindergarteners (PKs) and 5-6 kindergarteners (Ks). Four schools participated in the study. Three of the classes were attended by children aged 4, 5 and 6 years and one by PKs only. In all classes children worked in groups. Traditionally, group work gathers 4 to 6 students (Huber & Huber, 2007). In our study, groups of 5 students were formed. We considered that this is a number that provides good opportunities for interactions between members and for making different combinations of ages in a group. Considering that each individual child has a probability of interacting with each of the rest of the members of the group, we assumed that when the number of PKs is smaller than that of the Ks, each of them will have a higher probability of interacting with an older child. Thus, for the purpose of our study, we differentiated the number of Ks participating in the groups of each of the classes keeping the total number of members at 5 (all groups of a class had the same age composition).

In all the classes the teachers implemented science activities with topics from physics related to the states and properties of matter, the magnets, heat and temperature and motion and topics from astronomy related to the shpericity of the earth and the phenomenon of day and night (see Kallery, 2009 and 2011). Activities were hierarchically sequenced in order to support construction of meaning. Implementation started in October and ended in May. All teachers participating had a long experience in teaching science at the pre-primary level.

DATA COLLECTION AND ANALYSIS

Data was derived from two sources: a) Teachers' recordings made during all the stages of the activities' implementation and b) The post-instructional assessment of the students. In order to evaluate how each team member has benefited personally, children's assessment was individual. Assessments started in January, after the children had completed the first cycle of activities, and were carried out monthly until May. Teachers' recordings included: a) separate evaluation of PKs and Ks cognitive achievements in class, for each month from October through May, and b) the development of the communication-collaboration skill for each month.

The analysis of the students' answers to the post-instructional assessment classified them in two categories: 'acceptable' and 'non acceptable'. Acceptable answers were assigned the value 1 and the non acceptable the value 0. The percentage of the PKs' success for a specific evaluation task was then calculated. From these findings, the average percentage of the performance of these children was estimated. The analysis of teachers' classroom recordings was done in group sessions of the teachers and the researcher (author of the present paper). In this analysis, the teachers, based on their recorded information and the experience they gained from their interactions with the children, quantified the children's cognitive achievement assigning percentages for each month. The final value for the children's performance was found by calculating the average of the children's performance in the classroom and the performance in the individual assessments for each month from January to May. On the same basis, teachers quantified their recordings for the development of the communication-collaboration skill in the children providing for each month a percentage.

RESULTS

Results for both factors investigated were plotted for the younger children of each of the classes. Two representative graphs are these of Figures 1 and 2 where E_p is the PKs' performance. In these Figures graph B represents classroom data, C the individual assessments and D the average of B and C. The maximum value which the children's performance reached, as well as the point at which it stabilized is shown.

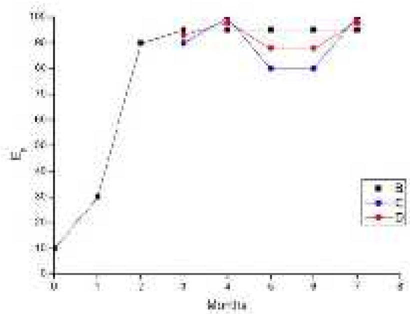

Figure 1. Performance of the PKs of a class with group composition 1PK and 4 Ks.

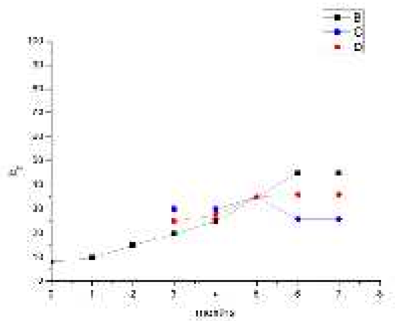

Figure 2. Performance of the PKs in the class attended by PKs only

These graphs also provide information on the length of the time in which the younger children of each class reached the maximum of their performance starting from the time they begun to collaborate with the older children in science activities. These findings were plotted and gave the graph of Figure 3. Evidently, the larger the number of older children in a group, the faster the younger ones reached the maximum of their performance.

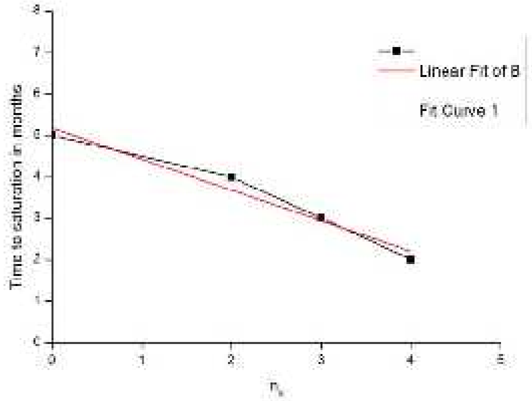

Figure 3. Time in which the younger children of each class reached the maximum of their performance in relation to the number of the older children participating in the groups of each of the classes

Similarly, graphs were plotted for the communication-collaboration skill. Two of these graphs are presented in Figures 4 and 5.

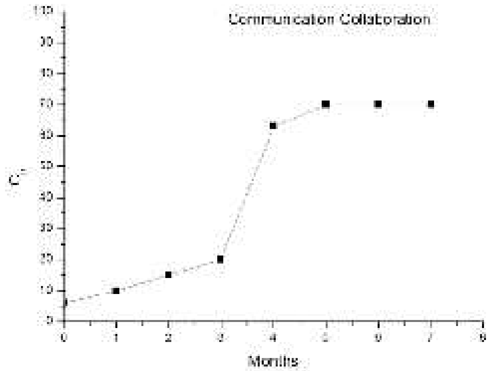

Figure 4. Evolution of the factor communication-collaboration in a class with group composition 3PKs and 2Ks

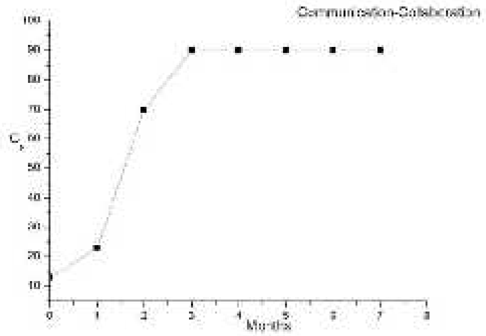

Figure 5. Evolution of the factor communication-collaboration in a class with group composition 2PKs and 3Ks

Using graph D the average performance for the months January to May for the PKs of each of the classes, as well as the uncertainty ranges of the average, were calculated. Plotting of these values gave the graph of Figure 6 which represents the performance E_p of the younger children in relation to the number of the older children n_k that participated in the groups of each of the classes

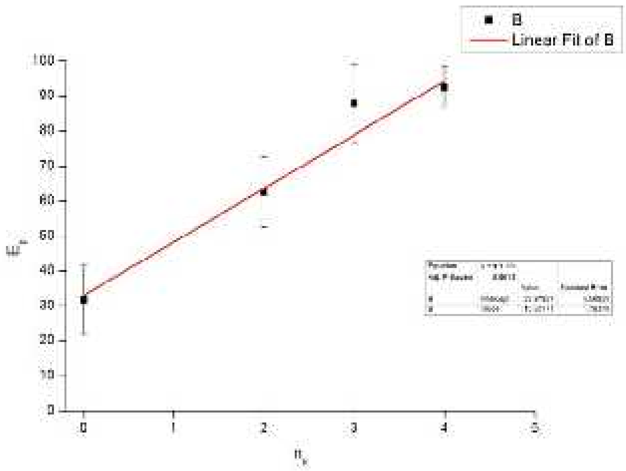

Figure 6. Performance of the PKs of each class in relation to the number of the Ks participating in the groups of each class

The graph of Figure 6 indicates that there is a linear relationship between the maximum of the performance of the younger children and the number of the older children participating in the groups of each of the classes. Based on this relationship the expected performance of the younger children of a class can be predicted depending on the age composition of the small groups of this class. These results were verified in two other groups of 6 members (formed in

two of the classes whose the number of students was not a multiple of 5 which had different age compositions (4Ks and 2Pks and 2 Ks and 4Pks) with very small variations (4% and 1% respectively).
Similar to graph of Figure 6 was the graph representing the communication-collaboration skill of the younger children.

CONCLUSIONS AND IMPLICATIONS

From the present study it can be concluded that in mixed-age small-group-learning in science, the age composition of the groups can significantly affect 'cognitive achievement' and 'communication-collaboration', and preferentially determine the time in which these factors reach their maximum value. The results can be interpreted on the basis of the findings of other studies reported in the introduction (Allan and Feldman, 1976; Peifer, 1971; Thelen & Kirkland, 1976) which have shown that younger children learn from the older ones, who constitute effective models for them. The present study not only provides qualitative verification of these interpretations, but also quantifies the role of the age composition of the small science learning groups of a class. Based on the above, the selective composition of groups with a larger number of older children who have more advanced communication and cognitive skills in science can be used to facilitate younger children's learning, as well as their social interactions (see Furman, Rahe & Hartup, 1979).

A DIDACTIC PATH FOR AGE 5-8 ON THE CONCEPT OF EXTENSIVE QUANTITY USING A STORY AS COGNITIVE TOOL

Cristina Mariani[1], Federico Corni[1] and Enrico Giliberti[1]
[1]Department of Education and Humanities, University of Modena and Reggio Emilia, Viale A. Allegri 9, 42121 Reggio Emilia (Italy)

Abstract. We present a didactical path for the introduction of the concept of extensive quantity using a story as medium. We assume that stories can be suitable for pupils aged 5-8 as emotional, cognitive and imaginative tools. Teachers can make use of stories as a methodological scaffold, useful to design and lead the activities. The story, together with the experimental activity, can foster children's verbal production. Moreover we want to give teachers the ability to move from the level of the experimental activity and the pupil's verbal description of their actions to the level of scientific meaning of the same words/actions. This can be achieved providing teachers with a series of examples of words and phrases that pupils may use, and have to be recognized as indicative of the relevant concept.

Keywords: Early science education, extensive quantities, story, semiotic mediation, substance-like quantity

INTRODUCTION

Teachers' elementary ideas on physics have been investigated (Kruger et al., 1992; Greenwood 1996; Atwood et al. 2001), showing that they often share the same alternative conceptions of their pupils. This fact is often considered as negative. However, the results of cognitive sciences and cognitive linguistics in articular (Johnson, 1987), show that at the basis of human thinking, and so also of scientific reasoning, are some elementary and fundamental concepts shared by the everyday experience. These concepts, called image schemata by some authors, are pervasive and emerge in language, at any level of formalization, from common language to scientific language. This means that, at least at primary school level, science education can rely on these elementary concepts, to develop them in order to base the scientific concepts that will be utilized for higher grades of instruction. In early science education the image schema of substance is fundamental, because by one hand it is the most basic gestalt that children (and adults) use spontaneously to represent and describe the reality seen through everyday experience, and on the other hand it represents a fundamental element for the formal scientific knowledge (Fuchs, 2007). The substance image schema corresponds to the scientific concept of extensive quantity.

An image schema is used to make meaning by metaphorical projection onto phenomena (Lakoff & Johnson, 1980). The figurative-metaphorical thinking characterized by fantasy, rhythm and narration, images, storytelling and emotionality (Egan, 1986) is the main source for the formation of hypotheses, which are required for interpretation and modeling of experimental activities. Literature suggests the use of stories and storytelling to promote emotional (Egan, 1989; Campbell, 1996) cognitive (Egan, 1989; Ellis, 2000) and imaginative (Egan, 1989; White, 1981; Klassen, 2007) involvement of pupils.

Bringing stories into science teaching derives from the evidence that an effective learning is achieved if children are both cognitively and emotively involved (Bruner, 1994). Pupils, under the guidance of the teacher which should suggest inquiry questions and help them to evolve their thought, take so an active role in building knowledge through formulation of hypotheses or explanations, identification of problem variables, hypotheses testing (Mariani et al., 2010).

In our approach the story represents also the way to help teachers from a methodological point of view. It represents a sort of scaffolding of intellectual steps and practical activities to focus on the elementary recurring concepts that are the goals of the didactic path. The story, according to this approach, acts as a background element, which fosters the ability both on the creative-imaginative and on the logical-deductive sides.

In this paper we draw a proposal for a didactic path, inspired by semiotic mediation framework for the mathematics laboratory activity (Bartolini & Mariotti, 2008), on the concept of extensive quantity, in which meanings are constructed through teacher guided stories, experiments and class discussions.

AIMS

The main goal of this didactic path is to introduce pupils of age 5-8 to the achievement of a good mastery of the concept of extensive quantity. In our aims, this path represents a methodological framework in which children and teacher can work together.

A STORY ON SUBSTANCE-LIKE QUANTITY: "RUPERT AND HIS FRIENDS AT THE LUNA PARK"

In this path we focus on the three aspects (properties) of the substance-like quantities:

1) Production/destruction
2) Transfer (distribution and accumulation)
3) Conservation

The "Rupert and his friends at the Luna Park", composed of various episodes to be used in different lessons, is the first of a series of stories that accompany the children through the years of primary school. On the methodological side, teachers are invited to design the activities following the path of the story, but they are free to modify and plan the activities according to their own specifications and needs. The teacher relies upon the story to set the correct sequence of steps, starting from simple to the more complex concepts. In the story, as substance-like quantity we choose the ice cream, which can be used, with different levels of interpretation, to show all the three properties. Moreover, it can be considered both a mass and a countable (ice cream balls) substance. We propose the use of a story containing few episodes showing different situations in which a group of friends are at the amusement park and they deal with ice cream balls. Some properties of the substance-like quantity are investigated at different levels, during the different episodes of the story.

At the beginning, the main characters that lead the pupils through the episodes are presented. Children can identify themselves with these characters and are involved in the solution of the problems that the characters meet, trying to ensure their help. The main characters who are the protagonists of all the episodes are: Pico, who represents "The Little Scientist", curious, attentive, ready to be amazed by the facts occurring around him, but also generous and always ready to help his friends when they meet some problems which they are not able to solve; Rupert, a frog, enthusiastic and curious, but always too quick to draw conclusions, often with awful results; Merlo, a blackbird, who, as a bird, can see the things happening from above, a sort of advisor for Pico and Rupert. The three main characters constitute a kind of emotional identification for the children's, but there are also some features that can be set on a more "cognitive" (or at least methodological) level: Pico, for instance, always brings with him a sketch book, on which he writes the accurate description of what happens, and suggests that pupils can do the same. He represents the "scientific method" and is able to formulate the "good" questions, so children are stimulated to do the same. Moreover, every episode of the story ends with a question posed by Pico, who asks for the help of the pupils to solve a problematic situation. Children in the class are both audience and actors of the story being told: in the beginning they watch the development of the story, but soon they are required to help the characters (Corni et al., 2010).

In the first episode the characters buy some ice cream and they wonder how much ice cream they have all together; after that, they start to exchange ice cream balls to try different flavours, and they notice that the substance can be compared and measured; in the end some ice cream exits the boundary of the amusement park.

In the second episode the story focuses again on the ways of making a comparison between different quantities of ice cream; moreover introduces the addition and the subtraction of ice cream balls, and the fact that when some ice cream balls fall on the ground they are not "eatable" anymore, so the total ice cream amount is reduced.

In the third episode the story introduces the proprieties of the countable quantities: the "transitive property" of the comparison.

In the fourth episode the story focuses on the difference between quantitative and qualitative (colour, flavour) aspects of a substance and try to differentiate them.

In the fifth and sixth episode the story presents different ways to verify the properties of substance-like quantities in the case of non countable substances, such as lemonade, or in the case in which counting is not sufficient to determine the amount (ice cream balls of different sizes).

HELPING TEACHERS TO INTERPRET PUPILS' PHRASES

An important goal is to help the teacher to move from the pupils' verbal level, to the recognition of the underlying scientific meaning. This can be achieved providing the teachers with a series of examples with some possible situations and helping them to recognize, according to the semiotic mediation framework (Bartolini & Mariotti, 2008), some "pivot words" that pupils may use, indicative of the relevant concept. For every situation, some examples of "pivot words" and possible situated text (sentences that teachers can expect that children will say/write) are given, with the related scientific meaning.

The following table is and extract of the compete table that suggests how the different properties of substance-like quantities can be recognized in the words of the children. The *situated text* shows examples of how the children can talk or write about the situation. The "*pivot words*" are the word that the teacher can use to recognize the reference to the specific property. The *scientific text* is the description, or definition, that the teacher can bear in mind and use as a reference (and doesn't have to be explicated to the children).

During the class discussion the teacher, starting from the situated text i.e. the pupils' phrases expressed in natural language, uses their "pivot words" to construct scientific meaning.

Property	**Situation/question**	**Pivot words**	**Situated text**	**Scientific text**
Production	The friends buy the ice cream from the ice cream man	The ice cream is made, the ice cream man prepares the ice cream	The ice cream man produces the ice cream from its ingredients and a recipe.	A substance-like quantity can be produced
Comparison	How can we tell who has more ice cream?	Number of balls, number of ice creams, comparison, to weight, to count	Counting the balls of ice cream we can say who has more. We compare the ice creams by means of their weights	Substance-like quantity can be measured and compared.
Transfer and	If someone gives one ice cream ball to	Number of balls, one more, one	If I give one ball to you, I will have one less and you will	A substance-like quantity can be

conservation	somebody else, how is the total amount of ice cream?	less, comparison, the same, altogether, transferring, giving/receiving, adding/subtracting	have one more. The ice cream amount that I give you is the same that you receive. The total amount of ice cream remains unchanged.	transferred preserving its total amount.
Transfer and conservation	If somebody leaves the park do we still have the same total amount of ice cream?	Number of balls, amount of quantity, transferring, total amount, park boundaries, inside, outside, before, after	The total amount of substance is the same, if we take into account the quantity both in and out of the park.	The amount of a substance-like quantity in a particular system increases or decreases according to the amount passing through the boundary.
Destruction	What happens to the ice cream when it is eaten or it drops on the ground?	Ice cream disappears, it melts, it is digested	The ice cream can change and become melt or decomposed.	A substance can be destroyed

CONCLUSIONS

We have outlined a didactical path for pupils aged 5-8 to introduce the concept of extensive quantity using a story as medium. We assume that stories can be suitable as emotional, cognitive and imaginative tools. Teachers can make use of stories as a methodological scaffold, useful to design and lead the class activities. The teacher has to be trained to recognise "pivot words" in the classroom discussion to become able to guide pupils from the situated level of description to the scientific level of giving meaning to things. Possible experimental further research could investigate the ability required by the teacher to use such a framework. Moreover, it could be useful to design analysis grid to interpret pupils' verbal and written productions to assess effective learning.

IDENTIFYING AND ELABORATING EMERGENT SCIENCE WITHIN A HOLISTIC APPROACH TO THE FOUNDATION PHASE CURRICULUM

Linda McGuigan and Terry Russell[1]
[1]University of Liverpool, U.K.

Abstract: The paper describes the research-based design of a 'Child Development Assessment Profile' (CDAP) for use by practitioners in the Foundation Phase in Wales. The need was for: i) a holistic perspective on development; ii) high quality, comprehensive support materials that defined clearly the behavioural criteria selected as the focus for attention (acknowledging their value in continuing professional development) iii) the manageability of all procedures and iv) the added value that the introduction of the CDAP would contribute to practice in planning and professional development. The broad age range addressed by the CDAP invited its use for the original benchmarking remit, but also for assessment for learning. The use of the CDAP as a tool for practitioners' planning was made possible by the close integration of the behavioural criteria with continuous provision in settings, the emphasis on developmental progression, and the mapping of developmental trajectories to end of phase designated Outcomes. Some features of the CDAP relevant to emergent science are discussed. Given the holistic intent, aspects of the six domains by which the CDAP is structured are enabling of other capabilities. Others have a much clearer bearing on aspects of scientific thinking. The authors describe the potential for the CDAP as a tracking device for practitioners and as a developmental research tool for science educators seeking to identify and nurture behaviours relevant to emergent science.

Keywords: emergent science, early years, assessment, progression

BACKGROUND, FRAMEWORK AND PURPOSE

'Emergent science' is recognised increasingly as an area for serious consideration within early years education. In England, the commitments enshrined in the Early Years Foundation Stage (2008) include encouraging children's play and exploration to promote active and autonomous learning through which children choose and find out for themselves new ways to do things (Tickell, 2011). Similarly, the Welsh Government has prioritised the fostering and support, through innovations in its education system, of independent, metacognitive and autonomous learners with an emphasis on skills development. An innovative 'Foundation Phase' framework is currently being implemented across Wales with a distinct shift away from formally structured and timetabled curricular demands towards a more child-centred provision. It is in this context that the authors were contracted to develop a Child Development Assessment Profile (CDAP).

The CDAP is to be used statutorily to assess children's capabilities on entry to the Foundation Phase. Entry must happen some time between the ages of 36 and 60 months. The instrument will, in addition to benchmarking on entry, have formative and diagnostic use in tracking children's development.

The development process adopted a collaborative, research-based design, inclusive of practitioners and subject to iterative formative evaluation. Expert validation was emphasised. Assessments had to make good sense to practitioners in terms of the behaviours they were attempting to promote amongst the young children in their care. The R&D procedures also paid careful heed to the issue of manageability. The intention was to ensure the ecological validity of the assessment activities. The behaviours practitioners were asked to assess and the manner in which they were invited to assess them should not seem misplaced or exotic in the context of the settings in which they took place, so were designed around the very kinds of behaviour that it would be appropriate for practitioners to foster as integral to the spirit and practice of the Foundation Phase.

This CDAP remit required an extensive review of the literature relevant to early childhood development, calling on the published expertise from a range of disciplines: developmental psychology, neuroscience, paediatrics, etc. The intention was to identify established developmental milestones associated with norm-referenced information as key markers in the developmental assessment of outcomes in early childhood education. It was possible to draw on previous research in this regard (Kagan *et. al*., 2004; Evangelou *et. al.,* 2009; Welsh Assembly Government, 2009). The tentative prototype frameworks designed on the basis of relevant literature had then to be tested by practitioners for validity, reliability and manageability. This was achieved through several several iterations in order to arrive at a state that satisfied both the commissioning agency and other stakeholders.

Given the authors' special interest in science education, these broad empirical lines of enquiry offered an opportunity to reflect on and seek clues to the antecedents of what might be thought of as a more specifically scientific way of thinking within the holistic and informal learning context that was the required starting point. We stress that these science-specific aspects were not part of the CDAP remit, but reflected our special interest.

RATIONALE

Within a holistic framework, we consider the characteristics of 'emergent science' that might be identified in the early years. The motivation for doing so is not to plead a special case for fostering scientific literacy or the production of future scientists. Nor do we seek to displace other curriculum special interests by favouring science, or suggest special programmes to identify prodigious talent, as happens in some subject areas (music, sports, the arts, etc.). Our intention is to identify science-relevant behaviours that might be the subject of nurturing attention through an analysis of appropriate pedagogical content knowledge (PCK). We seek to sharpen the focus of the kinds of intervention that might be possible to foster 'scientific thinking' across the variety of Foundation Phase settings. We speculate on learners' progression in the science-relevant capabilities identified and anticipate the means by which practitioners may facilitate their further development. The holistic context within which specialist science interventions can be promoted is accepted explicitly. The interrelated nature of the different areas of learning and development are understood and it is acknowledged that children's early education must be broad and expansive, based on as wide a set of experiences and expert support as can be made available.

METHODS

There are two distinct methodologies to be reported in this work.

The first methodology is the *empirical* grounding in the form of the development of a 'Child Development Assessment Profile' (CDAP). This happens to have taken place in Wales (and was therefore developed in bi-lingual Welsh and English forms). Although there will be divergent views in the priorities present in any country's early years curriculum, there is also a large degree of consensus, so much the same processes might have taken place anywhere internationally.

The second methodology is more conjectural, being the *theoretical* mapping between the generic capabilities to be supported and assessed in the early years and the typical constituents of science-specific curricular expectations. We try to avoid a parochial stance by referring to what we consider to be some general characteristics of science curricula for younger children. This theoretical mapping is an attempt to identify

the antecedents of science-specific behaviours

the manner in which progression in those behaviours might be described, and

the kinds of responses or interventions practitioners might plan to support and foster scientific thinking

Empirical Element

This two-year CDAP R&D programme commenced with a desk review of the Welsh Government Foundation Phase policy documents and guidance, supplemented by evidence from relevant international cognitive-developmental literature. Consultation and expert validation with representatives of all stakeholder groups was undertaken. Small-scale and large-scale trials (n= 128 settings, 503 children, Nov. 2009) and a national pilot (n=269 settings, 1195 children 24-94 months, April 2010) informed the development and refinement of assessment criteria and the structuring of the domains to be observed and assessed. Practitioners were invited to implement draft guidance materials and to assess their children's capabilities using the materials. Their assessments were analysed and their qualitative feedback coded and classified. The authors acknowledge that individual children's progress may not be smooth (Siegler, 2005). Nevertheless, it can be argued that developmental trajectories can be inferred from the empirical data, which focused on age-related progression of performance within criteria, the integrity and appropriateness of the domains for children's development and practical manageability. Outcomes led to a reformulation of the domains, refinement of criteria and elaboration of the supporting guidance materials.

RESULTS

The CDAP in its final form describes seven age-related steps, covering an age range of 30-84 months, within each of six domains, and totalling 114 assessment criteria. Detailed guidance materials include narrative descriptions of developmental progression in each sub-domain and detailed illustrations of the criterial behaviours. The range of providers includes child minders, playgroups and nurseries, some of these settings attached to schools and including practitioners who may have little or no relevant training or qualifications.

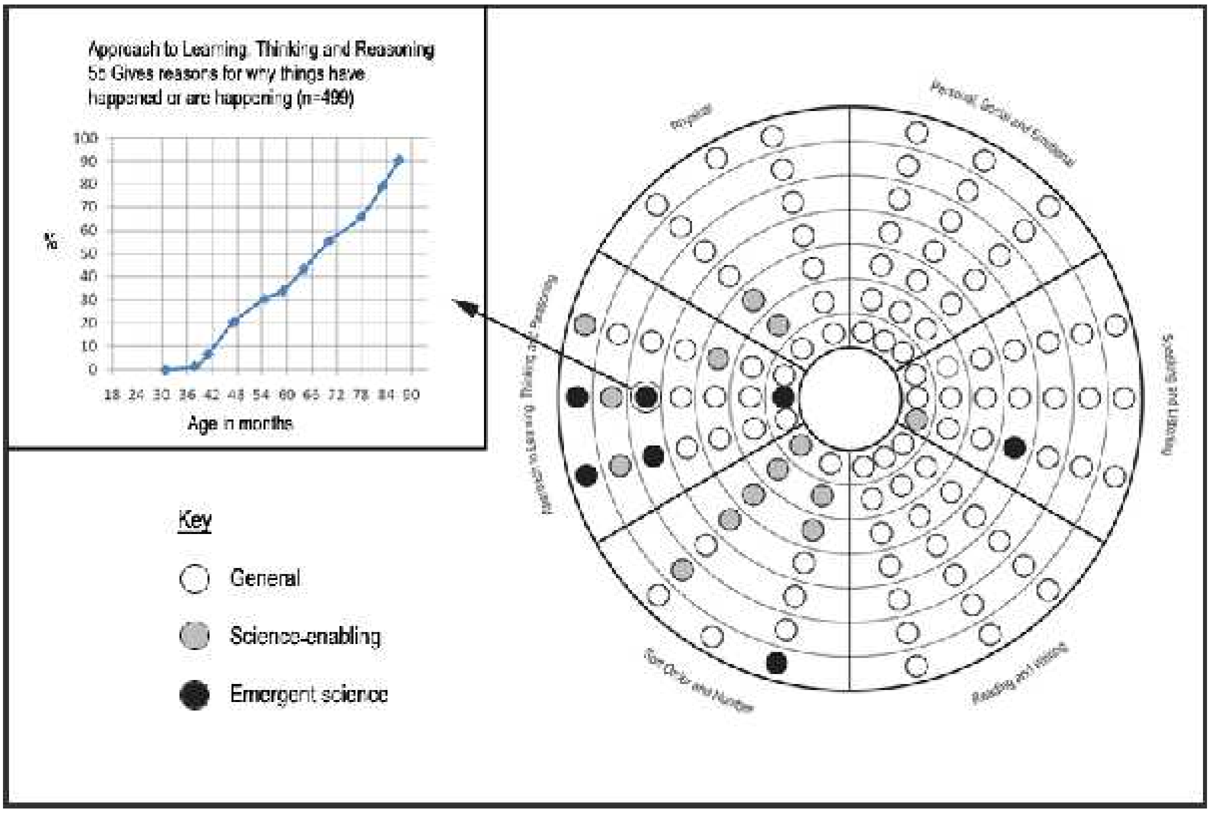
Figure 1 shows the design of 'Record Wheel' with its six domains of development: Physical; Personal, Social and Emotional; Sort, Order and Number; Approach to Learning, Thinking and Reasoning; Reading and Writing; Speaking and Listening. (Creative Development is treated as a cross-cutting theme.)

Each small circle represents an assessment criterion with progression in complexity radiating from the centre outwards in seven 'steps'. The inset graph shows the kind of cross-sectional-by-age performance data that was required to check developmental progression in any given attribute.

While a case might be made for the relevance of every domain and every criterion within it to emergent science, more stringent considerations have been applied. In Figure 1, emergent science criteria are shown as black circles, while science-enabling criteria are grey, with the remainder clear.

During the course of the CDAP development, researchers and practitioners identified illustrative examples of behaviours relevant to emergent science. In the space available it is only possible to illustrate how selected criteria in one of the domains, that of 'Approach to learning, thinking and reasoning', can be thought of as science specific. Each of the criteria used to assess children's developing capabilities within the domain are presented. The criteria selected as science specific are highlighted.

Figure 1. 'Record Wheel' for the Six Domains of Development



This developmental area identifies milestones in the development of the confident dispositions that enable the learner to take ownership of and actively influence their own learning and the learning of others. While many of the criteria in this area can be thought of as making a general contribution to children's development such as the capability to persist in the face of challenges, there are several criteria that can be argued to represent science relevant behaviours that might be the subject of nurturing.

1a Curious to know what is inside boxes and containers

1b Looks for or orients towards a dropped object*

1c Uses objects as intended

2a Maintains attention for about one or two minutes on a chosen activity

2b relates an experience today to one that happened in the past

2c Experiments with effect of own actions on objects and people

3a Shows curiosity about their wider environment and wider surroundings

3b Uses actions or words to indicate why one activity is favoured over another

3c Describes experiences or objects in speech, drawing, modelling, construction, movement or music

4a Remains engaged in an activity for at least 10-15 minutes at times

4b Remembers events in the past and uses these to anticipate events in the future

4c Takes on pretend roles and situations…

5a Chooses to work on a project because the activity is of personal interest

5b Gives reasons for why things have happened or are happening*

5c Can explain how things might change, given changes in circumstances*

6a Copes with reasonable challenges, shows persistence…

6b Can hold more than one point of view

6c Can describe a sequence of events in a logical way

7a Reflects on and evaluates the strengths and scope for improvement in their own work

7b Plans the steps in an enquiry and explains decisions about the approach*

7c Explains if a story is real or make believe, when prompted*

Criteria 5b and 5c are associated with the development of causal reasoning. The reasons children offer for events may not always be correct. They may be based on prior experiences, limited evidence or imagination. Nevertheless, in such instances children are showing a willingness to think about effects and their causes. These behaviours can be thought of as science relevant and can be harnessed and nurtured accordingly.

Similarly, children's capabilities to 'plan the steps in an enquiry' might be thought of as a milestone in the journey towards planning an approach to a scientific enquiry. Children's early planning skills might gradually evolve from the more general sequencing of steps to include some of the characteristics of managing a scientific investigation such as the identification and management of variables.

As might be expected, the identification of indications of science-specific criteria is not straightforward. The ways in which capabilities in various domains mutually interact and influence development has to be recognised. Some criteria that are important for science such as, 'Can hold more than one point of view', although associated with one domain in the generic CDAP call upon a complex set of behaviours when analysed from the science-specific perspective. For example, language development has an important role to play in the oral expression of ideas and the child's developing capabilities to ask questions, consider different viewpoints and seek evidence. Willingness to express ideas, to suggest ideas for enquiry and to engage in debates around the meaning of evidence requires not only language and communication skills but also a developing sense of self as an individual having ideas. In this context, the development of a 'theory of mind' (ToM) with a sense that others may have different ideas is a critical emergence. Children will need social and emotional competence so that they can participate effectively in discussions in which they make suggestions, offer explanations and perhaps give feedback on other children's ideas. Differences in the ways children explain their thinking or call upon evidence to explain how they know might be influenced in turn by their reasoning and number capabilities.

CONCLUSIONS AND IMPLICATIONS

This paper has described an approach to the establishment of an holistic assessment framework for children in the Foundation Phase and from this, has identified some science-specific indicators which might be present in early years provision. There are grounds to suggest that the CDAP provides a developmental framework that might be used by researchers and practitioners to explore systematically science-specific interventions in early years practice.

Research into the benefits of early years education (Sylva et al., 2008) suggests that its *quality* must be the overriding concern, not simply its presence or absence. This being the case, the identification of the antecedents for later scientific modes of thinking should equally compel a consideration of the quality of associated experiences and interventions. Kallery *et al.* (2009) sound a warning in suggesting that in their early years research, ‘the didactical activities analysed did not promote scientific understanding’. There remains work to be done in identifying emergent science and in enhancing the quality of didactics in the form of planned and targeted evidence-based interventions to facilitate its development. The provision of practical, open-ended experiences advocated in the early years curricula cannot be assumed to be ‘high quality’ or ‘enabling’ in terms of developing scientific thinking until we have clearly identified what behaviours are relevant, what they look like in the context of continuous or targeted provision and how practitioners might respond in ways that foster scientific ways of thinking in young children.

In addition to its use as an assessment for learning (AfL) tool, the defining of assessment domains and observable behavioural criteria argue for the CDAP instrument’s use as a developmental research tool for science educators.

FROM FICTION STORYBOOK TO SCIENTIFIC MODELING: AN EXAMPLE IN PHYSICS TEACHING AT PRIMARY SCHOOL

Mohamed Soudan [1], Jean-loup Hérau [2], Catherine Bruguière[3] and Eric Triquet[4]
[1234] S2HEP, EA 4148, Université de Lyon, Lyon F-69000, Université Lyon 1, Villeurbanne, F-69622, France

Abstract: This contribution is part of an interdisciplinary research about the use of storybooks in order to design and implement teaching sequences at primary school. We call these storybooks "realistic fiction" because they mix together fictional elements and scientific knowledge. Our thesis is that modeling the physical world of fiction is a relevant tool for modeling the physical world of our reality. This contribution shows that the storybook "*Plouf !*"[1] provokes an epistemological questioning among 7-8 years old pupils. The sequence operated semiotics substitutions in order to understand the notion of mass and construct a model bridging fiction and reality. The dialogues in the class show the ability of students to discuss the conditions of validity that the situations in question, fictional and real ones, should complete from the physical point of view.

Keywords: Realistic storybooks; Modeling; Physics; Primary school

INTRODUCTION AND AIM OF THE RESEARCH

We are engaged in an interdisciplinary collective research and we are studying the use of storybooks in science learning at primary school. We call "*realistic fiction"* a category of storybooks in which the fictional world and the real world overlap and are mixed together (such as *Fish is fish*, L. Léonni (1970); *Plouf,* Corentin (1991)) (Bruguière et al., 2007; 2009). In these books, the story follows the usual narrative fiction rules (personifying, intrigue, episodes), but it is not completely unreal, because it collides with the resistance of laws of nature (such as physical and biological phenomena). Consequently, these fictional storybooks implicitly contain some elements (questions, facts, knowledge) which agree or conflict with the scientific interpretation of the phenomena of the world. But there is no intention to popularize.
Our contribution is to show how the storybook "*Plouf"* (Splash) can be used by a primary school teacher to provoke epistemological questioning which leads pupils to construct a model of the underlying physical situation in this "*realistic fiction"* story.

ISSUES AND THEORETICAL FRAMEWORK

Fiction as contextualization in science learning

Several researchers consider fiction as a representation of a possible world, "whose function is to provoke, for a reader, the imagination of some content" (Barberousse et Ludwig, 2000). Following these authors, we argue that the fictional storybooks cannot be reduced to pure entertainment of the mind. Also, in the fiction, the reader does not get out the real world to

[1] *Splash* is the English translation of *Plouf.*

join an arbitrary or fantastic world. It is the contrary. Fiction does not directly question truth or falsehood, but it is not unreal, because it cannot escape from all the constraints of the real world. Far from being an illusion, it creates a possible world that provides a playful immersion which ensures adherence of the reader (especially pupils) to the physical situation (Shaeffer, 2010). The reader makes sense of fiction only if he has some collateral experience of his world. So, this content indirectly informs us about the structure of our world. This fictional function introduces us to the modeling process. Lewis (1973), in the context of his theory of “possible worlds”, argues that there is a “comparative similarity” between the counterfactual worlds of the fiction and the real world of our experience.

In this perspective, the fictional world has a double function of involving pupils and developing their imagination: Shaeffer (2010) calls it “imaginative involvement” or “make-believe”. Shaeffer claims that the fictional narrative leads readers into the real world through the world of the pretense, so that they are able to question the real world from cognitive perspective.

Consequently, this kind of storybook plays a very important role in the epistemic construction of student’s scientific knowledge. Thus, the fiction content provides an imaginative extension of our world which can be used by the teacher. Thus, pupils can question the representative function of fiction from the underlying physical situation. It engages them into the modeling process. The Lewis’s theory of possible worlds is a relevant theoretical framework that justifies our choice to use fictional storybooks as a context for scientific inquiry in science education. It is a conceptual tool to examine “Truth in fiction” (Lewis, 1971) and truth outside the fiction and their relationships.

Cartwright (1983) argues that a “model is a work of fiction”. In this sense, model is not immediately given in the physical situation which is itself (re)constructed, but it has to be imagined and constructed by means of signs (Soudani et al., 2009). Modeling, particularly at primary school, is always controlled by the experience. Thus, using fictional storybooks with students leads them, as much as possible, to experimental reasoning which develops both imagination and manual skills, involving linking and mutual tests of hypothesis, new languages (i.e. modeling in a semiotic sense), and designing and manipulation of new experimental devices.

Epistemological issues of storybook "Plouf !": towards modeling activity

This storybook presents a fictional story that has a realistic side, otherwise it could not serve as educational tool. *Plouf* is a “realistic fictional story” which tells a story of a famished wolf. When roaming in the neighborhood of a well, he sees the moon reflection at the bottom of it. He mistakes it for some cheese. He bends and falls. He cannot go back up by himself.What can he do? A pig passes by the well. The wolf baits him and makes him using the well equipment (rope, pulley and bucket, only shown, never described verbally in the text) in order to get out of the well while the pig goes down the well. In the same manner, the pig will be delivered by rabbits who take his place. Finally, rabbits are delivered by the same wolf who finishes at the bottom of the well. Wolf and his prey pass each other by a counterweight phenomenon, and the wolf cannot catch any prey because he crosses them at high speed. Regarding physical law, the last episode is impossible, but pupils cannot perceive it. They have to be questioned about truth in this storybook.

We can consider this storybook from several points of view: First it’s playful and moral, secondly there is a scientific background about biological and physical phenomena. It develops the intelligence by means of the imagination’s development. As scientific educators and teachers, we focus on its scientific role. *The aim is to make pupils pass from superficial*

reading (playful, moral) to scientific background (well, rope, pully…). As Schaeffer (2010) said, fiction assures an imaginative implication of pupils as an integral part of the activity of scientific modeling of the perceived world. Halbwachs (1974) tells us that "*in any physical situation of the "real world", it will correspond with physical science* […] *one (or some) "signs" systems, which consist of figures, graphs, mathematical symbols, or more simple propositions formed with words. It will then be assumed that these systems will represent the situation. Such system of signs, we shall give the name of model*"*.* Modeling consists of substituting a set of signs to the material elements of the concrete situation in a way to manipulate signs instead of objects.
This requires an experimental reasoning which develops both imagination and hand skills, involving a development of relationship and mutual controls of hypotheses, signs system, designing and manipulation of new experimental devices.
Our storybook's *a priori* analysis shows that the basic steps of the modeling activity can be connected to its episodes. So, the teacher must be aware of the change in point of view, as shown in the diagram below, in order to guide pupils: 1) the first modeling stage consists of converting events of fiction into the underlying physical phenomenon. Pupils "create" signs (natural language) and use them to provoke this passage; 2) from characters register to material and physical objects register. This decisive second stage is to create other signs and use them to represent and to quantify relationships. Consequently, pupils make hypotheses about a regularity principle (law of physics). 3) In the third stage, this principle will be applied to test the coherence of the third episode.

The wolf bends: he falls into the well with the bucket	Gravity the intrigue condition = the phenomenon causality	From biological necessity (hunger) to physical action (mass and gravity)
The pig falls and the wolf goes back up	Phenomenon of the pulley: The pig is heavier than the wolf.	physical quantities and their relationships: The wolf mass (m_w), and the pig mass (m_p). $m_p>m_w$
The 3 rabbits fall and the pig goes back up	The three rabbits are heavier than the pig	$m_r>m_p$

Table1: First stage : converting fictional event

This process is a powerful way to help pupils easily modeling the physical situation of the real world: According to Lewis (1971) and to Schaeffer (2010) we can assert that modeling the world throughout fiction leads to modeling the real world.

MATERIALS AND METHODS: SEQUENCE AND DATA ANALYZED

Our goal is to provide imaginative and cognitive involvement of students and develop the thought experiments that transform the reading of the storybook into a problem solving sequence in an inquiry based approach.
We have two sets of data from sequences in two organized classes (7-8 and 5-6 years old). We reproduce below the main steps of the sequence with the 7-8 years old class, and the choices the teacher made. Each stage contains epistemological questioning that involves the modeling process. This questioning is linked to principal episodes of fictional narrative.
The teacher has a didactic choice, first by reading the whole storybook before giving any scientific explanation and then by adopting a constructivist framework. After leading an *a priori* analysis in our research group, we ask the teacher to dramatize the reading and transform the storybook into a problematic situation, in order to engage the pupils' reasoning.

Then we develop an experimental thought which compares and contrasts both fiction and reality. The goal is for the teacher to divide the story into five steps so that the pupils gradually investigate the storybooks and channel their epistemological thoughts into a modeling activity:
Step1: *Putting the story into words in order to convert the fictional events into physical phenomena. This needs specific and technical vocabulary. Like a translation, there is a need for new words to describe the phenomena.* The album has many images, but contains few words. Therefore the pupils have to design and describe, using their own words, the components of a water well, and imagine a coherent continuation for the story.
Step2**:** *Analogical modeling*. We go from formulation of hypotheses to building an analog and semiotic model. Going from characters to analogous counterparts, the pupils' task consists of conceiving, constructing and manipulating an experimental device using a rice bag, a pulley, and a rope in the classroom. This is done, so that they understand the pulley principle: by means of an artifact which is substituted for the images found in the storybook.
Step3: *Semiotic modeling*. Pupils have to construct a signs system in order to build a model (Halbwachs,1974): iconic and written symbols are required to pass from step2 to physical quantities and their relationships. They build a system of signs (as defined in Halbwachs, 1974 and Peirce, 1978) which replace the two situations (: fiction and device itself). So that students can answer this question: what conditions (*Physical Principle Formulation)* are needed to get out of the well?
Step4*: Testing validity of the model* into new problematic situations: in the storybook, how will the pig get out of the well? (Pb1), and under what conditions can the rabbits help the pig? (pb2). What mathematical and formal conditions need to exist so that the pig can get out of the well with the help of the rabbits?
Step5: *From Fiction to reality*: Is the model pertinent, verifiable, and able to be applied to other similar situations (generalization)? The teacher provokes an epistemological dialogue between pupils concerning the final image in the storybook. Can the wolf raise the rabbits? In which condition(s) is this possible? This picture contains an internal contradiction: the wolf is both heavier and lighter than himself.

We collected the data by video recordings we have transcribed. We have also collected the written productions of the pupils during their various tests. After, "E" will represent the Teacher, and "e" will represent the pupils. The extracts of dialogues in class raise(find) several episodes of debates; the numbers which follow each other belong to the same episode. Besides, involving rather of characterizing the phases of the modelling of the epistemological point of view more than the approach(initiative) of learning(apprenticeship) in a class, we did not make distinction between GS and 2nd year of primary school.

In the following, "T" is the teacher, and "E" is the students. The extracts of dialogues in the classroom are more episodes of debate, and the numbers that follow are in the same episode. Furthermore, with regard rather to characterize the phases of the modeling of epistemological point of view rather than the learning process in a class, we did not distinguish between GS and CE1.

MAIN RESULTS AND DISCUSSION

We consider step 2 of the modeling process above, in which pupils change the fictional situation (Fig.1) into a technical device in the classroom (Fig.2), by substituting an iconic sign (a drawing, Fig.3) for characters. The body of each character is replaced by the same sign (a drawing or an object that serves as a sign in order to quantify the value of their masses).

Pupils represent the mass of different characters with bags of rice that the teacher had brought in the classroom: students can then compare them in terms of “heavier/lighter”.
Another step consists of mathematizing this comparison by substituting the “*m*” alphabet sign (indicating the masses) to bags of rice, so that students can compare them in terms of “larger/smaller” or “higher/lower”, as shown in fig.4. Notion of mass –that is the common property of all physical bodies- is understood in this step, but not conceptualized by the pupils: they manipulate variables and terms of relationship.

Fig2: Experimental device elaborated for the classroom: analogical model

Fig3: Narrative of a group of students, and design of the concerned device

« Experiment of Plouf !

“First, we began by doing exactly what is in the text, but there are too many of strings, so we cut some out […] and we linked it to the trestle , there were 2 bags as well, in the one there was a lot of rice, and less rice in the other. The one containing more rice was the pig, the lighter one was the wolf. Then we tried to balance them, so we removed some rice from the pig. It is the pulley which is used to help with all that”

Fig4: Substitution of the bags of (identified by labels) to the correspondent characters of fictional story

The following extracts of the sequence illustrate the process of connecting quantities by pupils in order to interpret the movement of involved bodies: Teacher ask them about the “apparent” contradiction in the last scene

1. Teacher: "So in your opinion, will the wolf successfully raise the rabbits out of the well?

All pupils answered “yes” (2), except one pupil who said “no”(3). But the teacher has not asked him about his response. The exchange continues as following:

4. Teacher: “Really? But how will the wolf do it?
5. Pupil 3: Well! He will pull the rope
6. Pupil 4: no, he is hanging... he doesn’t pull.
7. Pupil 5: yes, because he is big
8. Pupil 4: he is heavier than rabbits
9. Teacher: Oh! are you sure?
10. p6: yes... he will fall into the well.
11. Teacher: Okay. Then we will test with what?
12. Pupil 1: (all) the pulley !”

Pupils presuppose (wrongly?) that the wolf is heavier than rabbits. The model they have built is still used, but limited to a couple of physical quantities. On the one hand, the teacher doesn’t question the pupils about what they have learned previously. According to our *a priori* analysis, teacher might, for this last scene, guide students in developing their intra fictional reasoning. However, she chose an extra fictional criterion. On the other hand, pupils don’t spontaneously operate transitivity relationship. In defense of pupils, it should be noted that we are dealing with living things whose mass can vary over time. In this case, the relation of transitivity can be questioned.

Teacher gives each group the pulley. Pupils manipulate and observe by doing the same manner as in previous sessions. They note that:

2. Pupil 1: “The wolf [he] can not ... uh ... he doesn’t succeed in raising the rabbits out of the well”

Some pupils think that rabbits are heavier than the wolf because there are three. Others think that: (12). Pupil 4 “bah, even if they are three, [et bah] ... they can be lighter”

After the discussion, the teacher summarizes the major opinion of the class:

16. Teacher: "So, rabbits cannot be delivered by the wolf because they are heavier than the wolf, not because they are three”. She proposes “Now we'll see what happens in the story”

1. Teacher: So, in the story, how does it work?
2. Pupil 1: Bah! The wolf helps the rabbits get out.
3. Pupil 2: yes he succeeded.
4. Pupil 3: in the story, the wolf is heavier.

Then, pupils are asked to discuss the validity of the two situations: around this exchange, there is the central epistemological question for this modeling activity: what can one question? The model? The fictional situation? The empirical physical situation?

5. Teacher: “So, is it true what is happening in the story?
6. Pupil 4: No...
7. Teacher: “Really?”
8. Pupil 4: ... with the pulleys it does not work.
9. Pupil 5: This is not the same [thing in the story].
10. Teacher: So in the stories, is it always true what that is told?
11. Pupil1(all): NO!
12. Teacher: So, everything said in the stories is not always true”

Here appears a central epistemological function of modeling, which sets up a dialogue between right and wrong about a problematic situation such as in this last scene. Dialogues show that pupils are able to talk about truthful conditions and that this situation should be valid from a physical point of view.

CONCLUSION AND EDUCATIONAL IMPLICATION

On the basis of the storybook *Plouf !* as a didactic support, and the Lewis' theory of possible worlds (1978) as a theoretical framework, we tried to demonstrate that the modeling of the reality *in* fiction and the modeling of the reality *by* fiction are interdependent: modeling the physical world of the fiction leads to model the physical world of the reality.
Consequently, the theory of possible worlds would be a way to question the reality and build a model that makes the real world an application of a field of possibilities. Models, as conceived today by the philosophy of science, are a construction of a possible reality, not a copy reducing or simplifying the real world. So, they are larger and contain more things that in the observable reality, which is contingent and singular.

One consequence that seems to be interesting for the physics education is that the model created in a given situation (real or fictional) allows to consider a range of possible situations and bridges the gap between them. In other words, modeling activity is involved in the physical world and in the fictional world: It enables students to compare them, discuss them and to assess their truth.

The advantage of this modeling work for pupils would be in the development of their capacity to interpret and evaluate truth in new physical situations: intra fictional (other realistic fiction storybooks), or non-fictional (as in Blanquet, 2010, for example).

THE RELATION BETWEEN CULTURAL BACKGROUND AND UNDERSTANDING OF PRECIPITATION AMONG 5-8 YEAR OLD CHILDREN

José Domingo Villarroel[1]
[1]The University College of Teacher Training in Campus of Biscay. The University of The Basque Country. Sarriena s/n, 48940-Leioa (Bizkaia). Spain.

Abstract: This paper presents an overview of initial results of a research line recently launched at the University College of Teacher Training in Campus of Biscay (The Basque Country) to examine whether preschool and lower grades of primary education understanding of natural phenomena (and more specifically, the mechanisms of rainwater) and, moreover, whether this comprehension differs according to the differences regarding the socio-cultural background of the children comprised in the sample (over a hundred of subjects).

Keywords: Early education, cognitive development, atmospheric phenomena.

The understanding of the mechanisms of rainfall during childhood.

Atmospheric phenomena and in particular rainfall, are widely used resources in elementary education levels for work related to both the natural sciences and metric aspects of mathematical understanding (Fernández & Rodríguez 2006 , Rossano & Schiller, 1995; Oramas, 1992, Plasencia & Varela 2006). However, the analysis of the evolving understanding of the mechanisms of rainfall during the early stages of school has received little attention, focusing the bulk of research on this subject towards students of higher educational levels (Tytler & Peterson 2004; Taiwo, Ray, Motswiri & Masen, 1999).

The few studies that have been conducted on this issue in early childhood education level show some common patterns especially related to the theme of the origin of rain. In this vein some scholars have pointed out that children tend to consider that clouds are different from water even though they accept that rain may be related to the appearance of clouds. Moreover, it has been said that children connect the sky to the generic place in which rainwater is created (Inbody, 1963, and Munn, 1974; Za'rour, 1976).

This project trys to identify and analyze the patterns of understanding of the mechanisms of precipitation at upper elementary education level (5-6 year old). Furthermore, the patterns found will be linked to the different cultural backgrounds of the children in the sample studied.

The learning process of the mechanisms of rainfall during early ages

Although the main barrier to the explanation of the mechanisms of precipitation is a lack of understanding of the concepts of the water cycle and, especially, the meaning of evaporation and condensation (Bar & Galili, 1994; Donaldson, 1973), it has been reported that these scientific concepts can be successfully taught as early as pre-school and first primary educational levels (Tytler & Peterson, 2004).

Furthermore, it has been demonstrated that early knowledge on the mechanisms that produce this rainfall is deeply influenced by the cultural framework surrounding the child, for example from cultural beliefs and pseudo-scientific knowledge plus the geographical location of the children (Miner 1992).

Moreover, what this research highlights is that from a very early age human beings try to make sense of both cultural, physical and biological phenomena that surround them. In this vein, several authors (Vosniadou, 1994, Vosniadou & Brewer, 1992) have emphasized that this cognitive attempt to make sense of the surrounding physical and cultural environment is carried out even from pre-school educational levels. Thanks to this cognitive effort children generate a way of understanding the real world which eventually provides them with a comprehensive framework which comes from the foundations of the comprehension of scientific models transmitted by scholastic learning.

Consequently, it seems reasonable that promoting a better understanding of the early interpretive models can be a useful attempt at the design of a more effective early scientific educational strategy. This could be true as bearing in mind children's explanatory contexts and new educational approaches are implemented from the child´s prior knowledge, meaning that this new knowledge will be constructed on the basis of the child´s existing knowledge (Christidou & Hatzinikida, 2006, Tytler & Peterson, 2004).

Objectives

The research presented in this paper aims to analyze how a representative sample of children at the final level of elementary education (5-6 year old) and first level of primary education (7-8 year old) understand the phenomenon of precipitation in order to detect: (a) different interpretive models (b) whether the children's cultural background and, secondary, sex and age, are related to the models displayed.

Ultimately, the main purpose of this research is to provide the field of early science education with more empirical data about how children under the age of 8 interpret very elementary concepts typically belonging to Earth Sciences. It also paves the way to the understanding of how social factors influence the grasp of these basic but indispensable notions. All these goals are thought to promote the idea of being able to design better educational proposals for elementary levels in the field of science education.

Method

The sample of the study comprises of 50 children from two public infant and primary schools located in the city of Vitoria (The Basque Country, Northeast Spain).

The age of the participants is therefore about the age of 5-6 for children at infant level and 7-8 for those who are at primary school. The sample is balanced in terms of sex ratio.

With regard to the data collection procedure, only age, sex, school and family origins were registered. The families whose children took part in the study were informed through the direction boards of the centers regarding the objectives and research methodology. The conversations with the children were recorded together with the drawings they made. No photos or video recordings were made.

A 10 minute, semi-structured interview was carried out with each of the children, using the following questions relating to the concepts to be investigated:

1. Have you ever seen rain?

2. And ... What is rain?

3. Where does rain come from?

4. How is rain formed?

5. Where does the rain go after it falls to the ground?

6. Sometimes after it rains there are puddles. Where does the water from the puddles go after it disappears?

7. Have you ever seen clouds?

8. What are clouds made of?

9. Did you notice whether clouds have always got or not, the same shape?

10. How do clouds change their form?(If applicable).

11. Do you want to tell me anything else you know about rain?

To conduct interviews and to facilitate communication with children the conversation is always initiated with a brief tale and then the researchers make use of a small puppet to encourage children to talk it regarding the aforementioned questions.

The interviews were carried out in Basque or Spanish, appropriate to the linguistic profile of the school.
